Reionization

dark ages

reionization

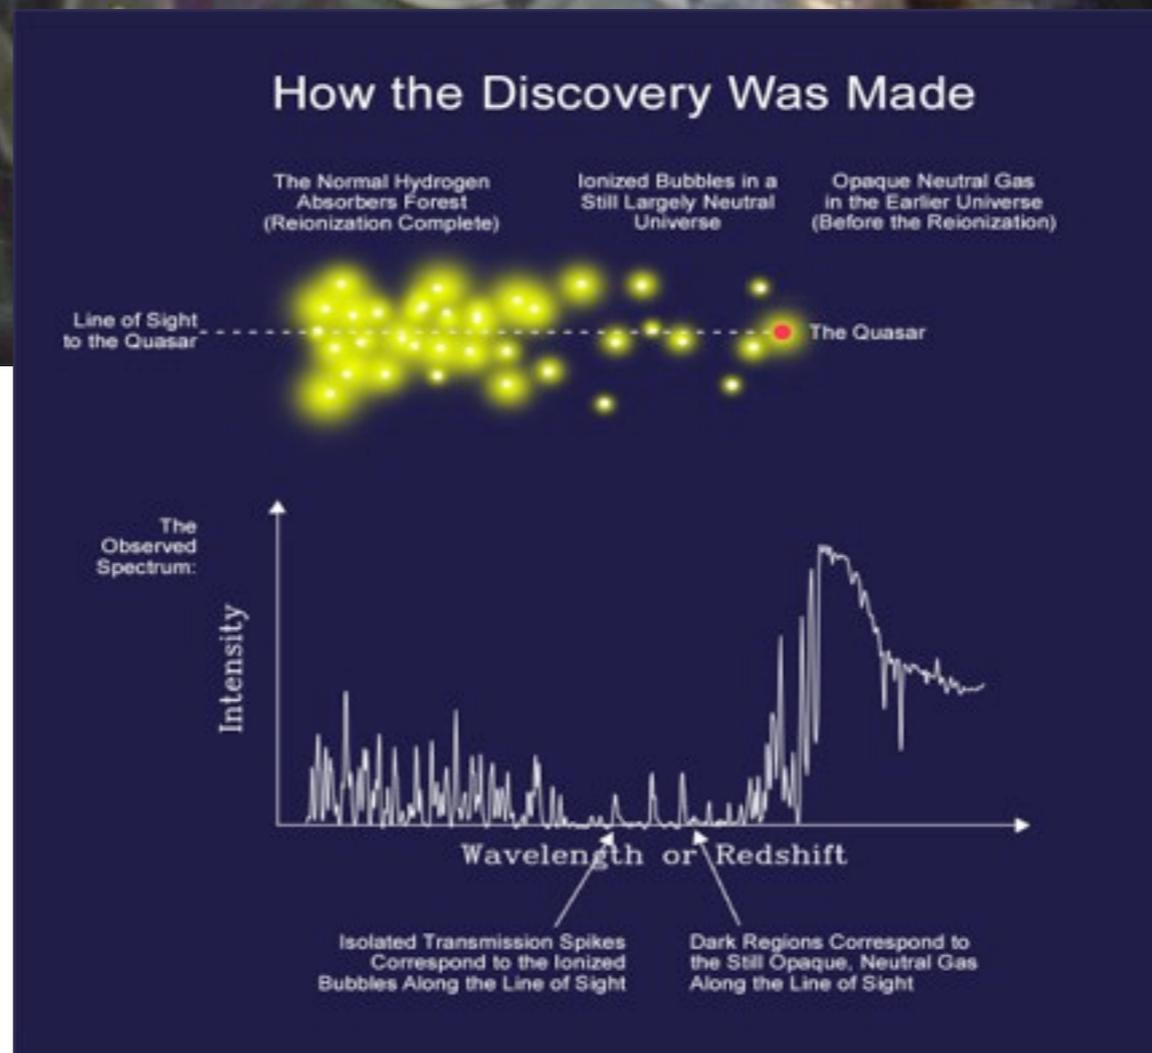

CMB

first sources
(stars ?
quasars ?)

first galaxies

Loeb, 2006

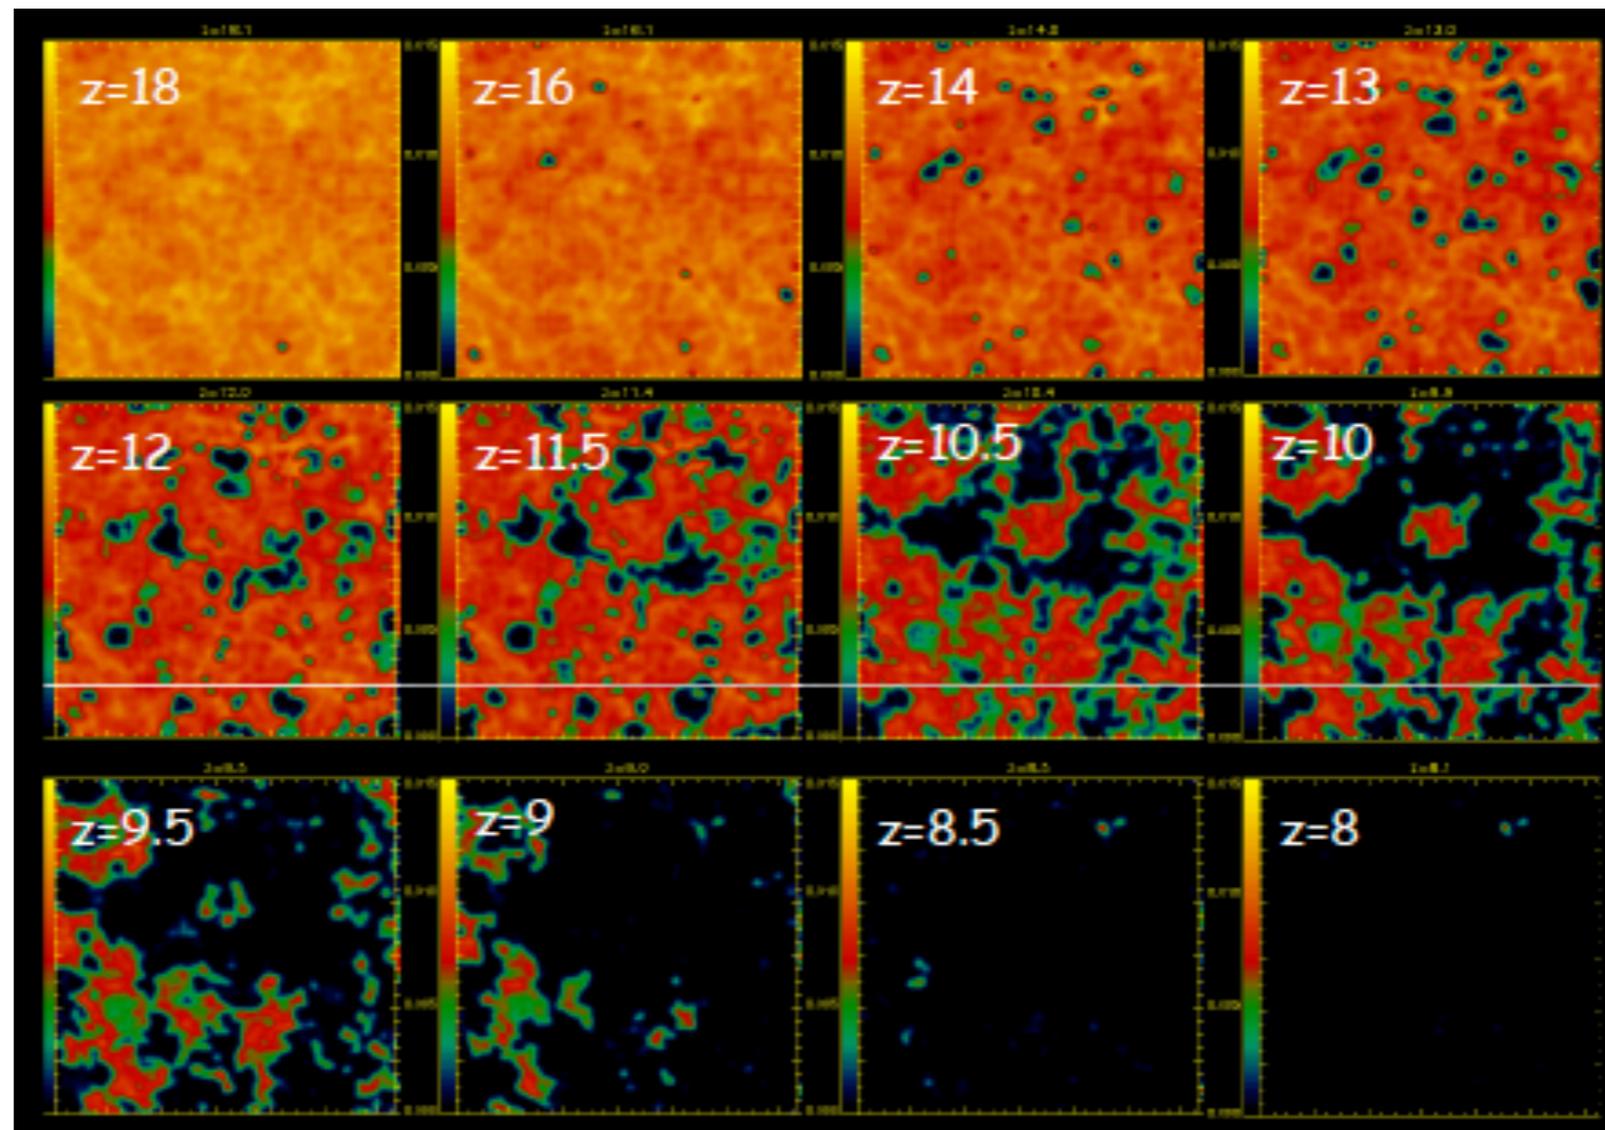

Djorgovski, 2001

Simulations

- First sources ? Initial mass function ?
- Simulations of structures formation including dark matter + ionization sources + radiative transfer (assumption dependent scenario)

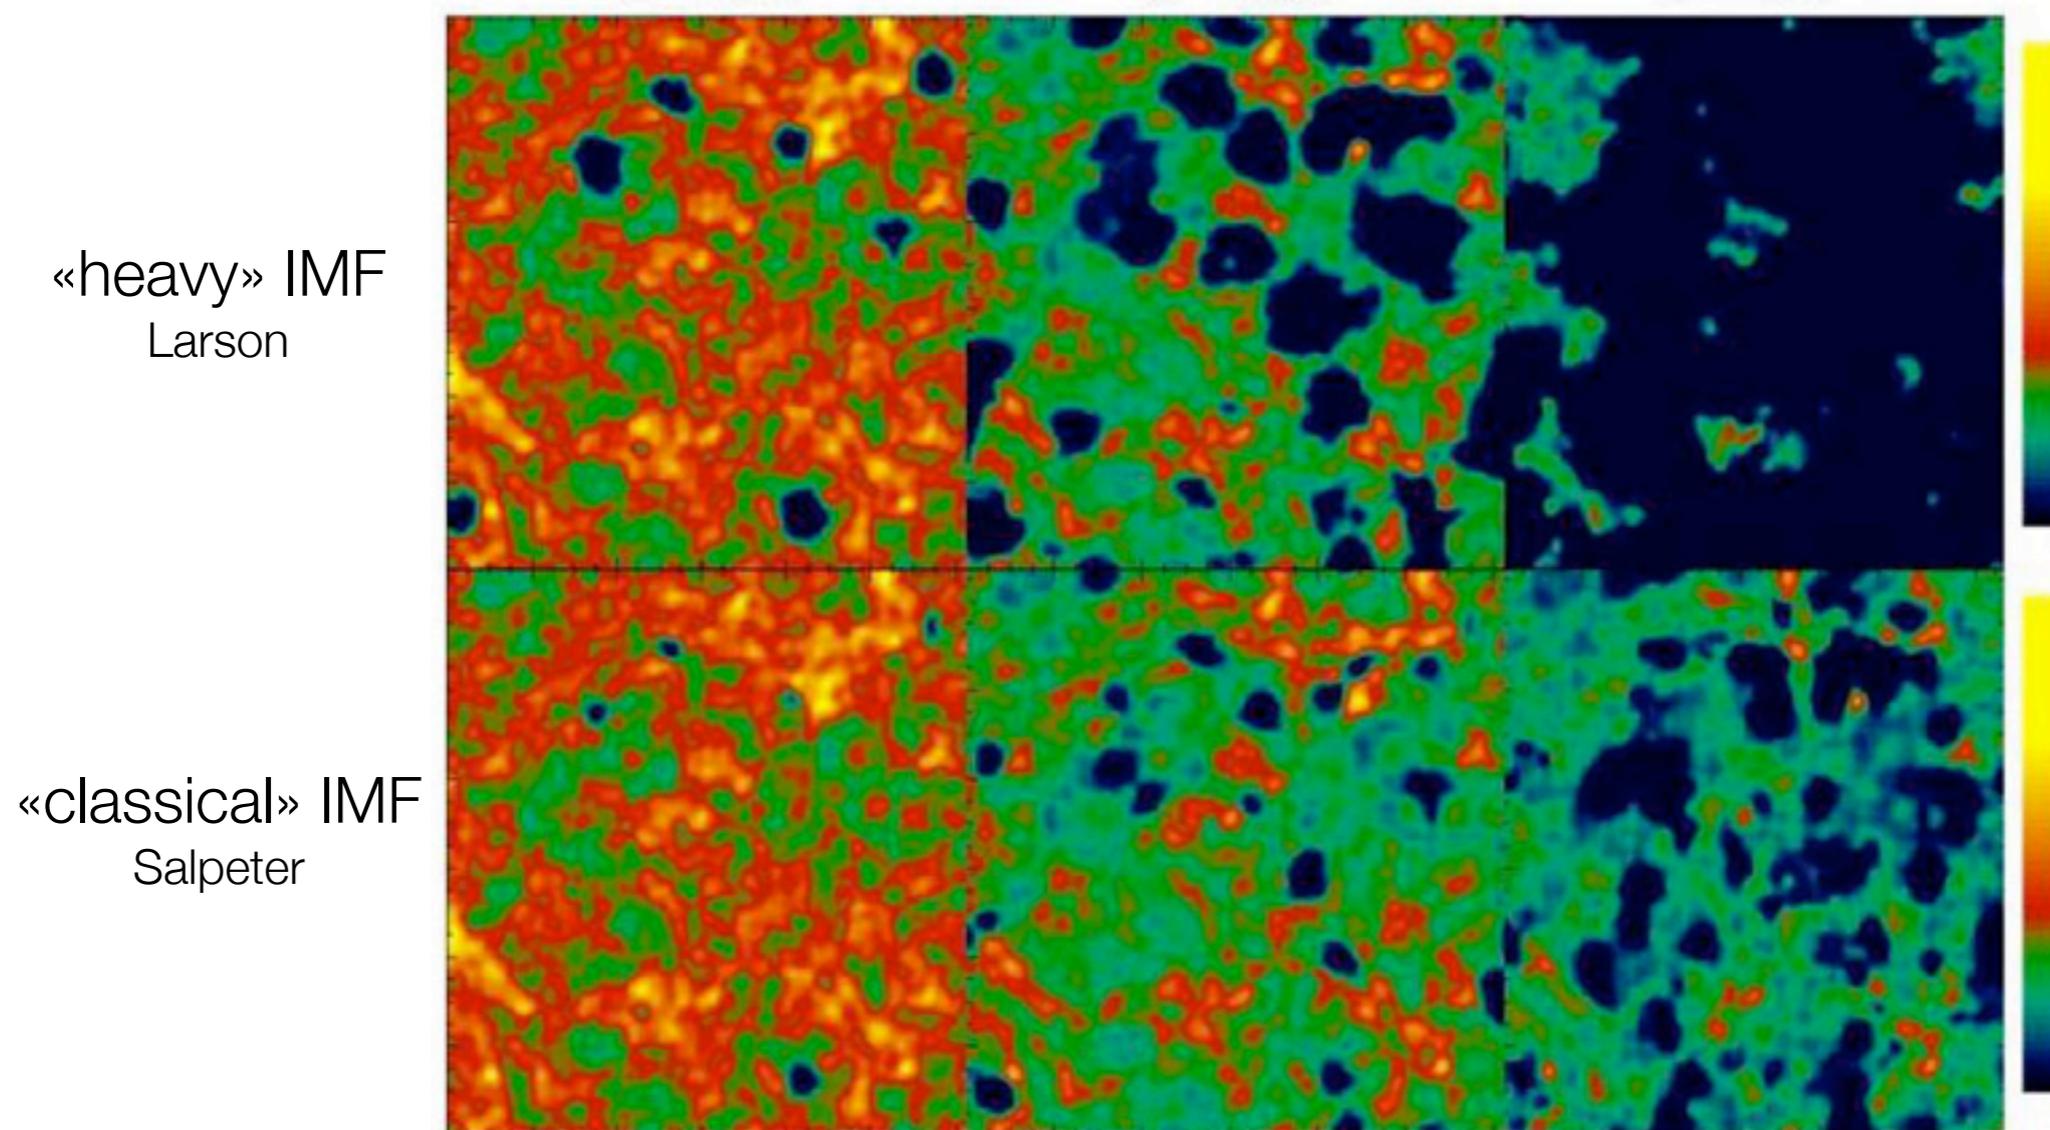

HI density

Simulations

- First sources ? Initial mass function ?
- Simulations of structures formation including dark matter + ionization sources + radiative transfer (assumption dependent scenario)

HI density

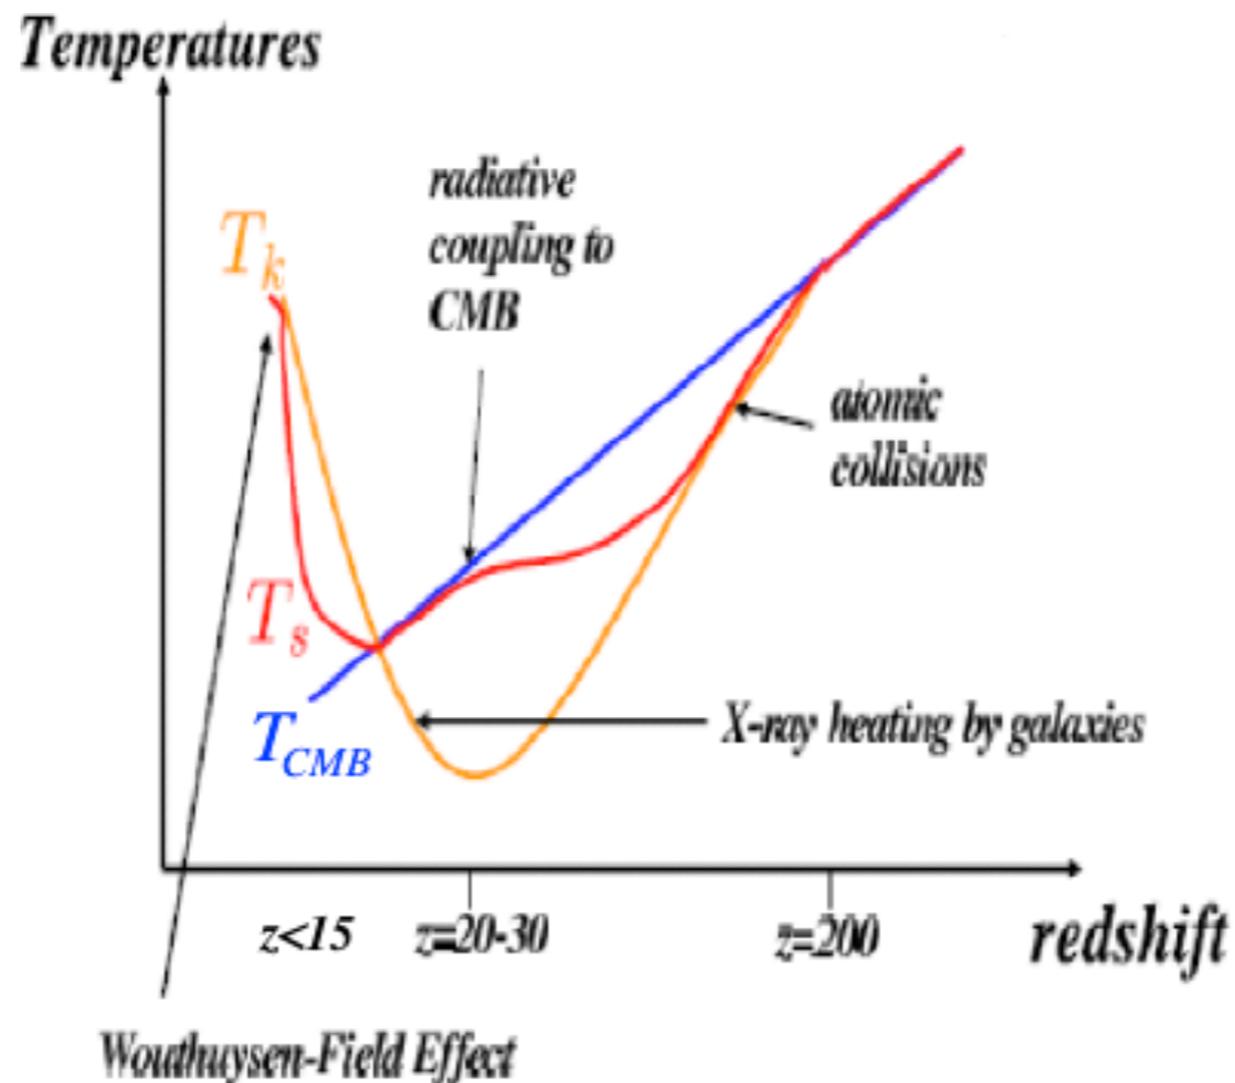

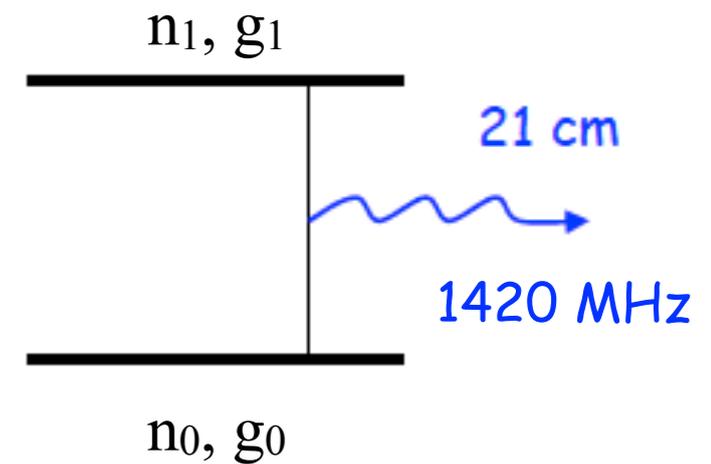

EoR Signal

- HI ground state hyperfine transition : $n_1/n_0 = g_1/g_0 \exp(-T_*/T_s)$

with $T_* = 0.068\text{K}$ and spin temperature $T_s(T_{\text{CMB}}, T_k)$

T_k = gas kinetic temperature \rightarrow collisions, absorption/emission of Ly- α photons (Wouthuysen-Field effect)

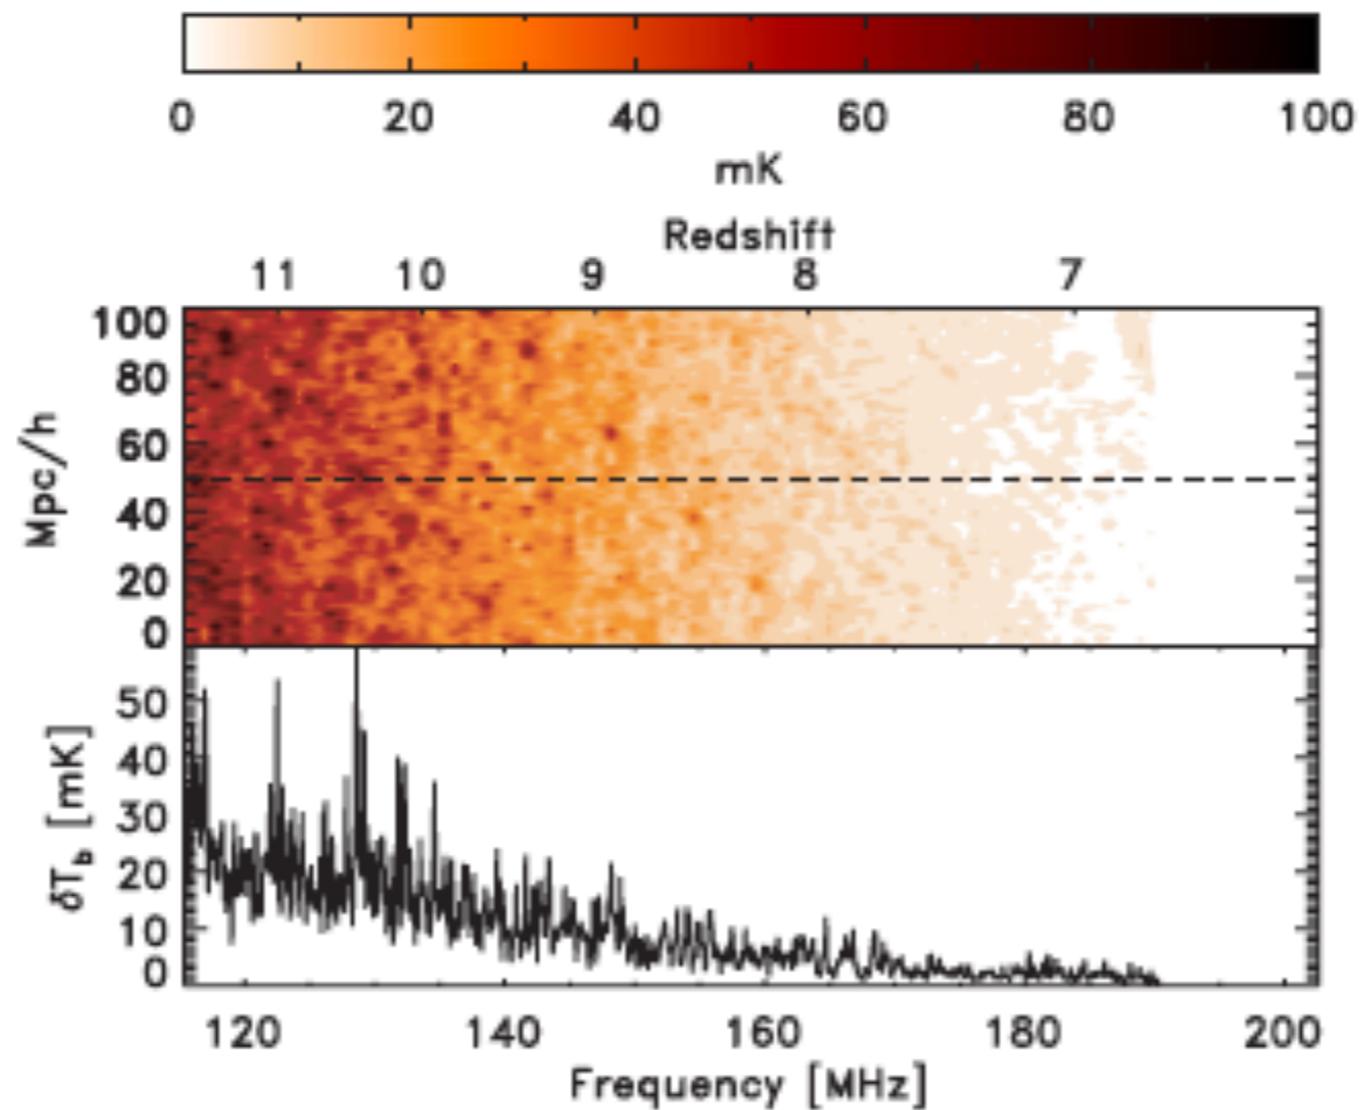

EoR Signal

$\delta T_b \sim (T_S - T_{\text{CMB}}) \cdot \tau / (1+z) \Rightarrow \sim 10$'s of mJy, in emission or absorption

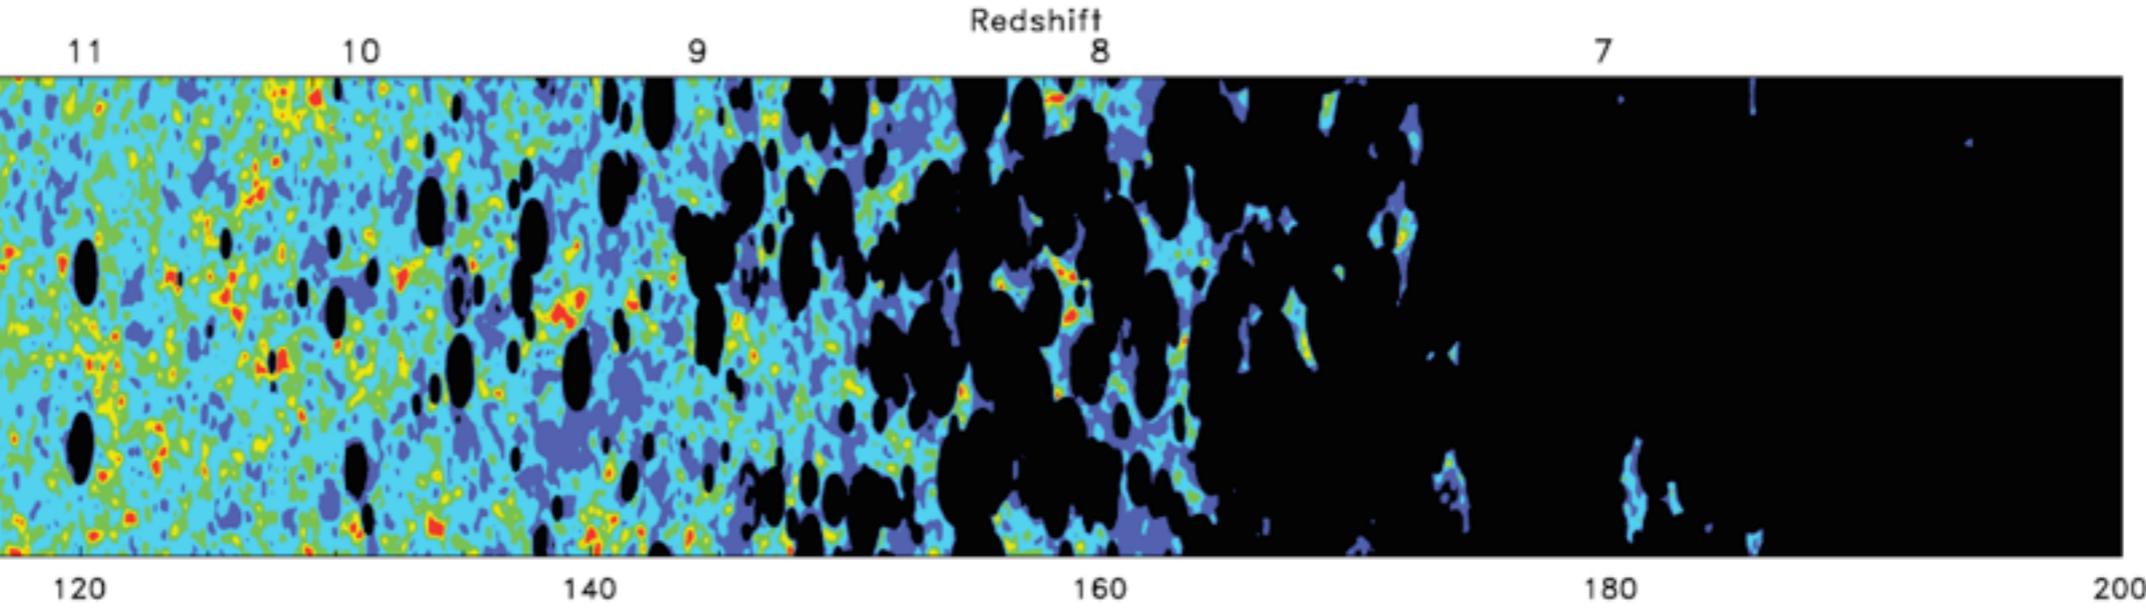

models \Rightarrow evolution of T_S , T_{CMB} , τ with z

\Rightarrow maps of δT_b vs $z =$ IGM tomography

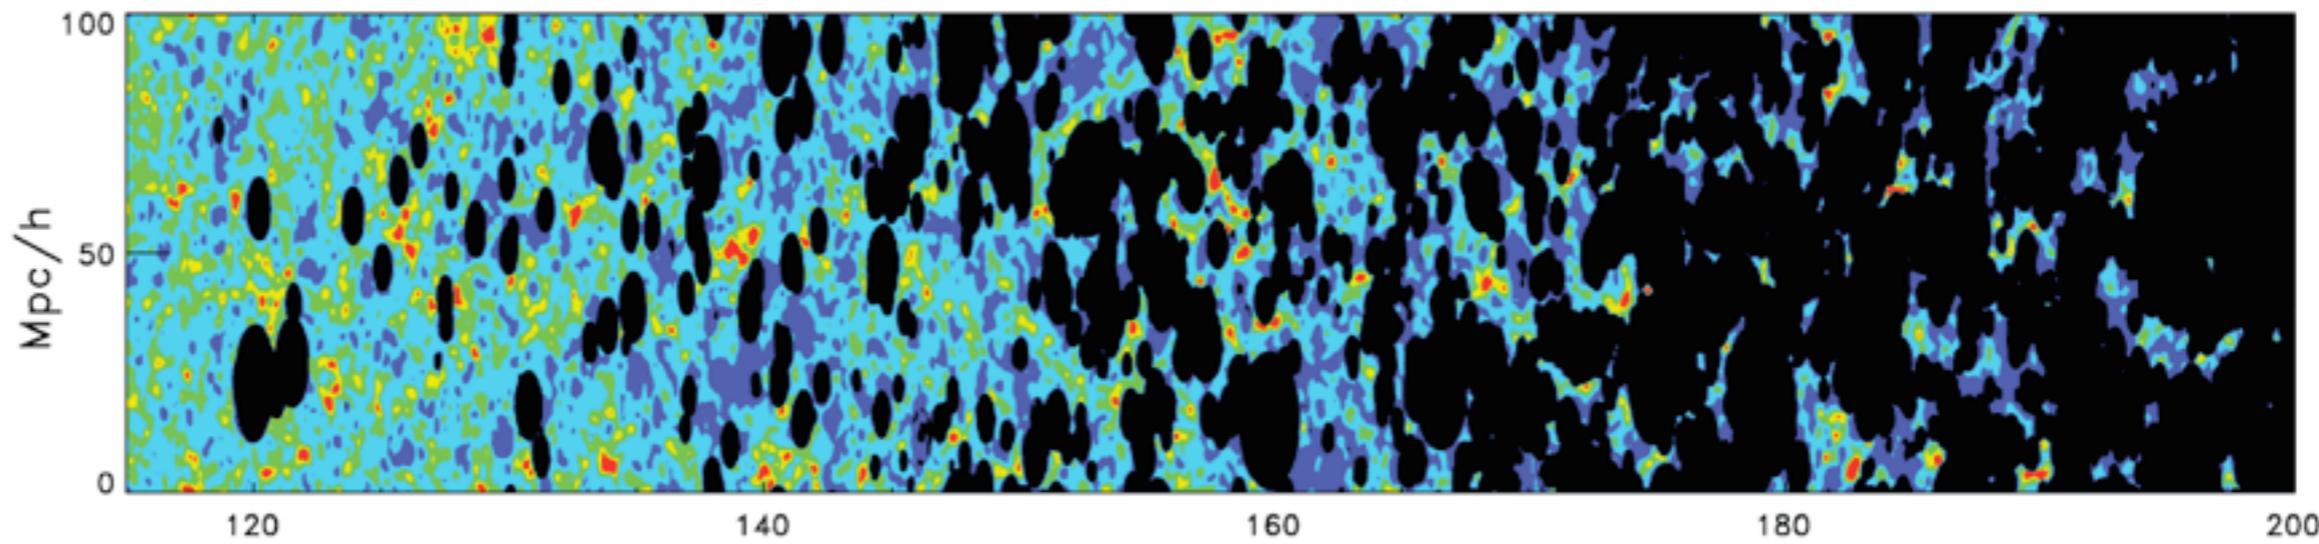

\Rightarrow typical structure size \sim arcmin

EoR Signal

First sources = quasars

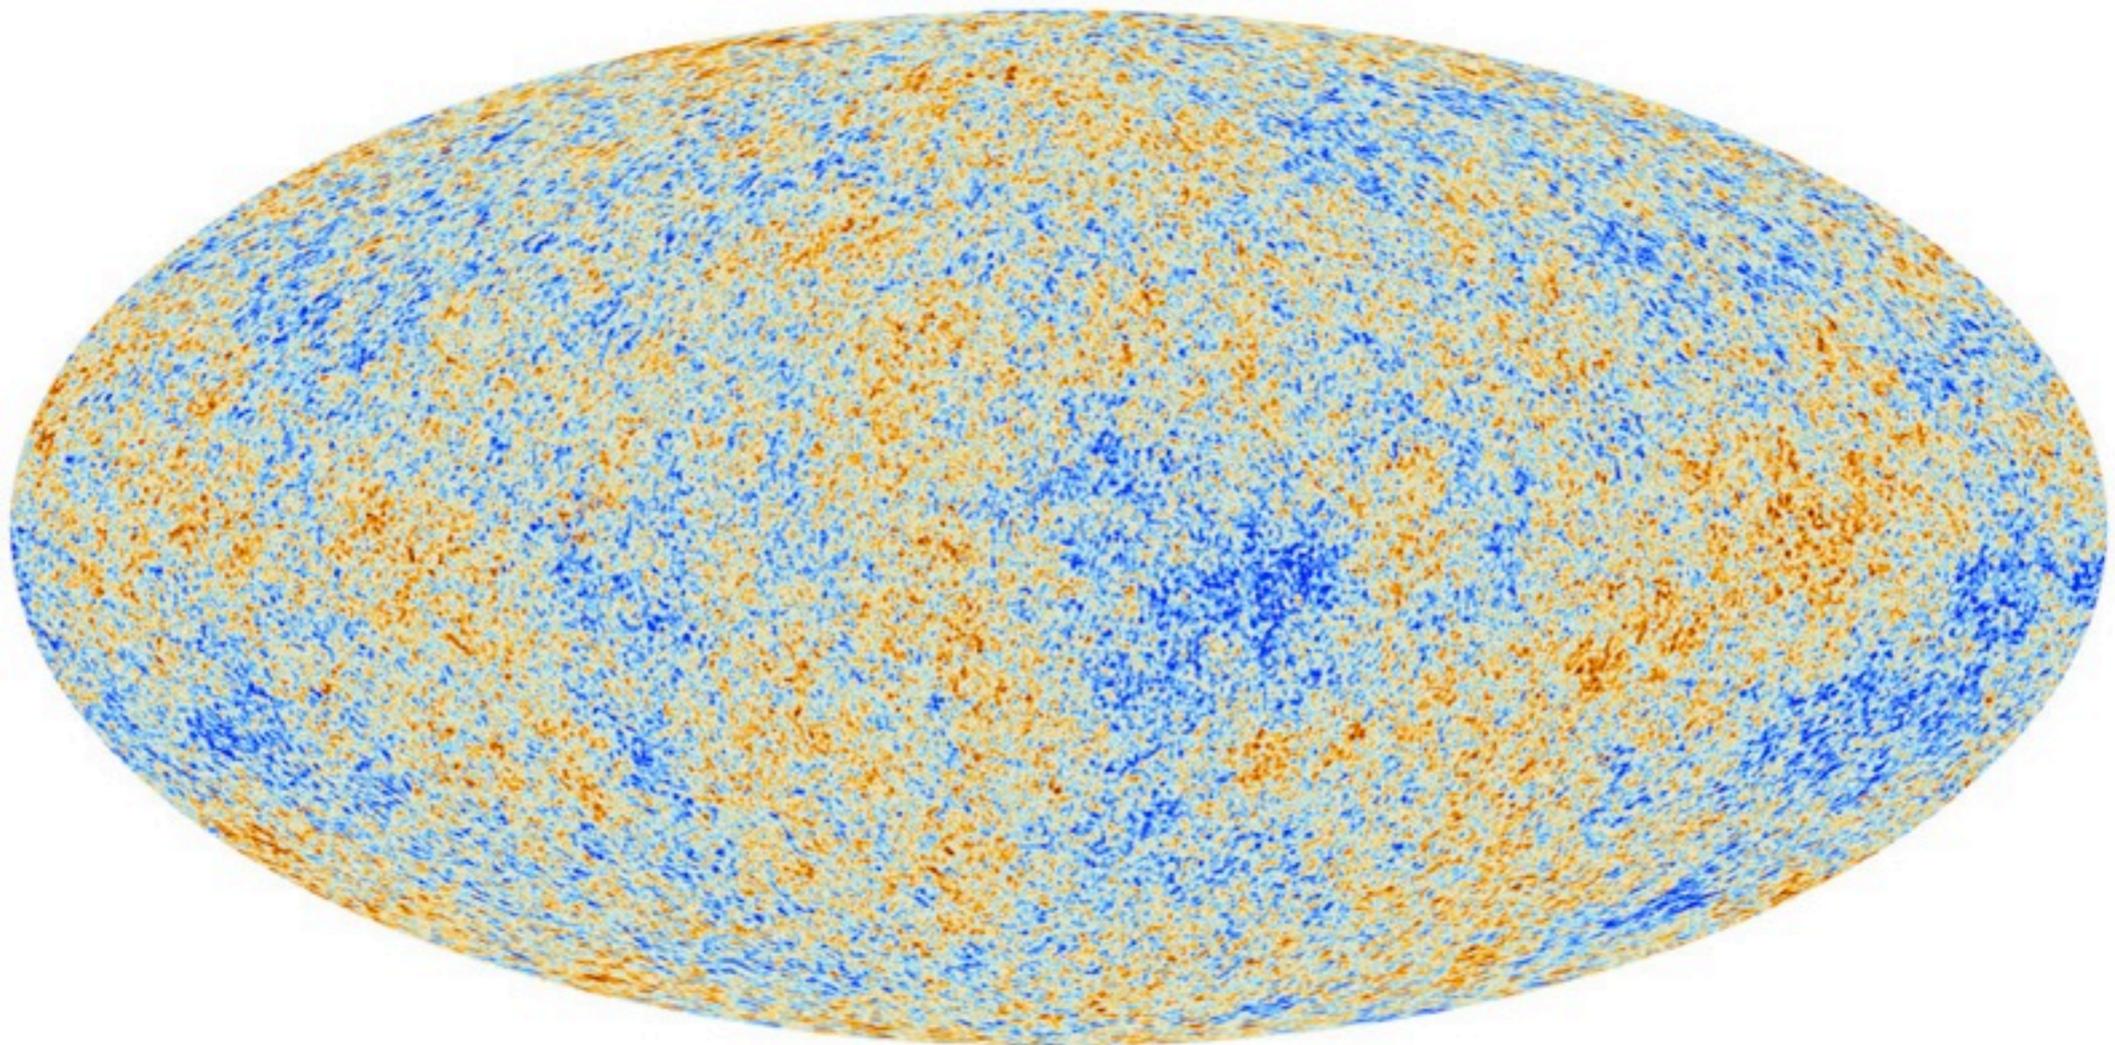

First sources = stars

Interest of EoR signal detection

- First sources ? Initial mass function ?
- Dark matter ? Super Massive Black Holes at high z ?
- Density power spectrum during dark ages
- Cross-correlation δT_b (21 cm) with CMB & Ly- α emitters maps
- Distribution & characteristic size of bubbles ?

Zaroubi, 2008

Planck map, 2013

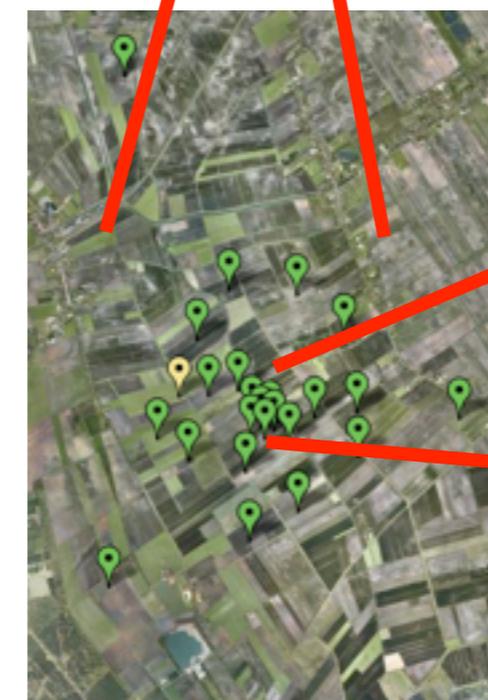

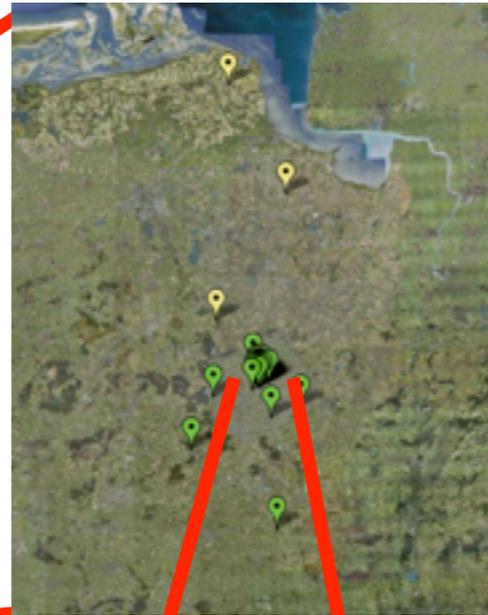

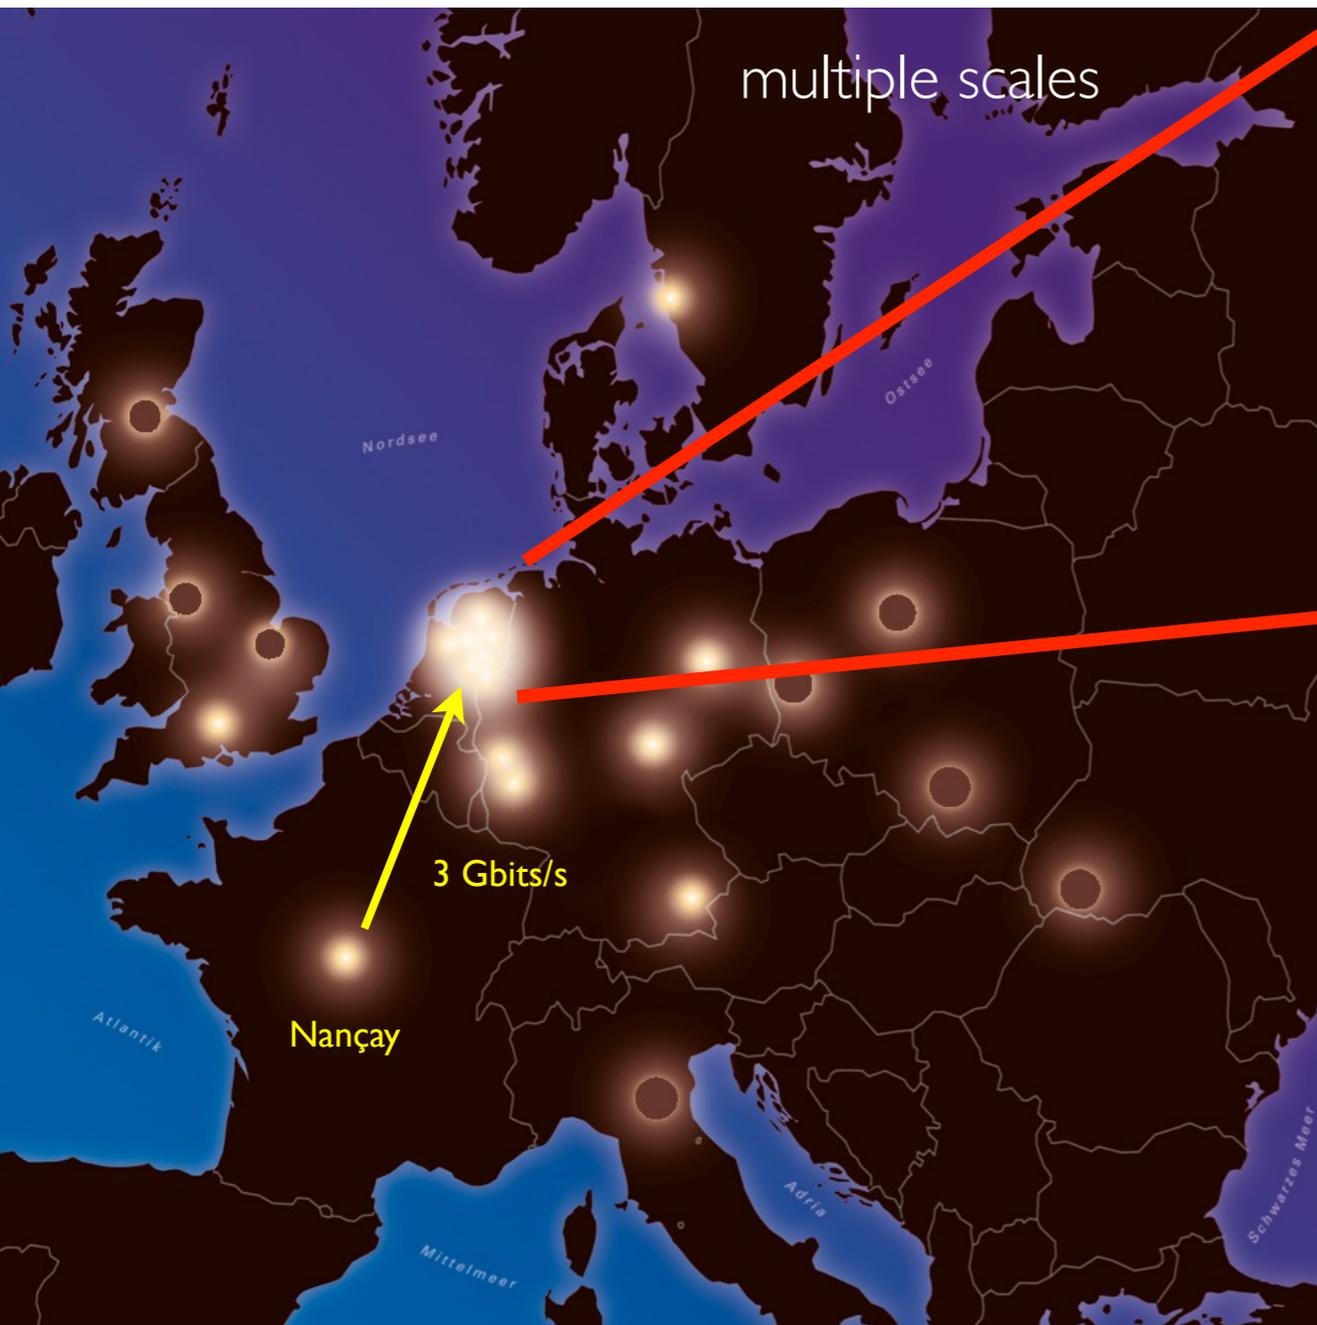

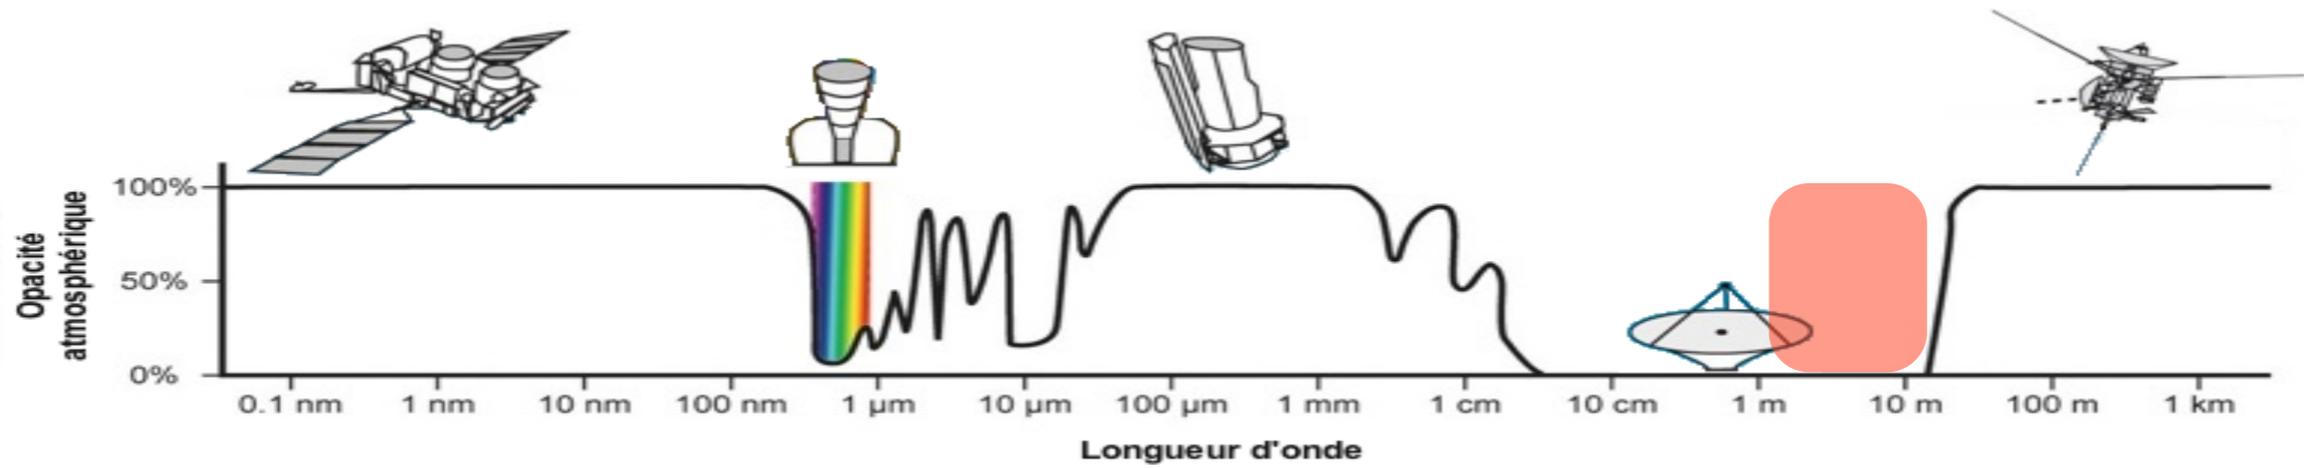

Required instrument

- maps of δT_b (redshifted 21 cm) vs z = IGM tomography with sensitivity \sim 10s of mJy & arcmin resolution
- $z = 6 - 12 \Rightarrow \nu = 110 - 240$ MHz , $\lambda = 1.2 - 2.7$ m

Low frequencies : LBA
(30-80 MHz)

High frequencies : HBA
(110-250 MHz)

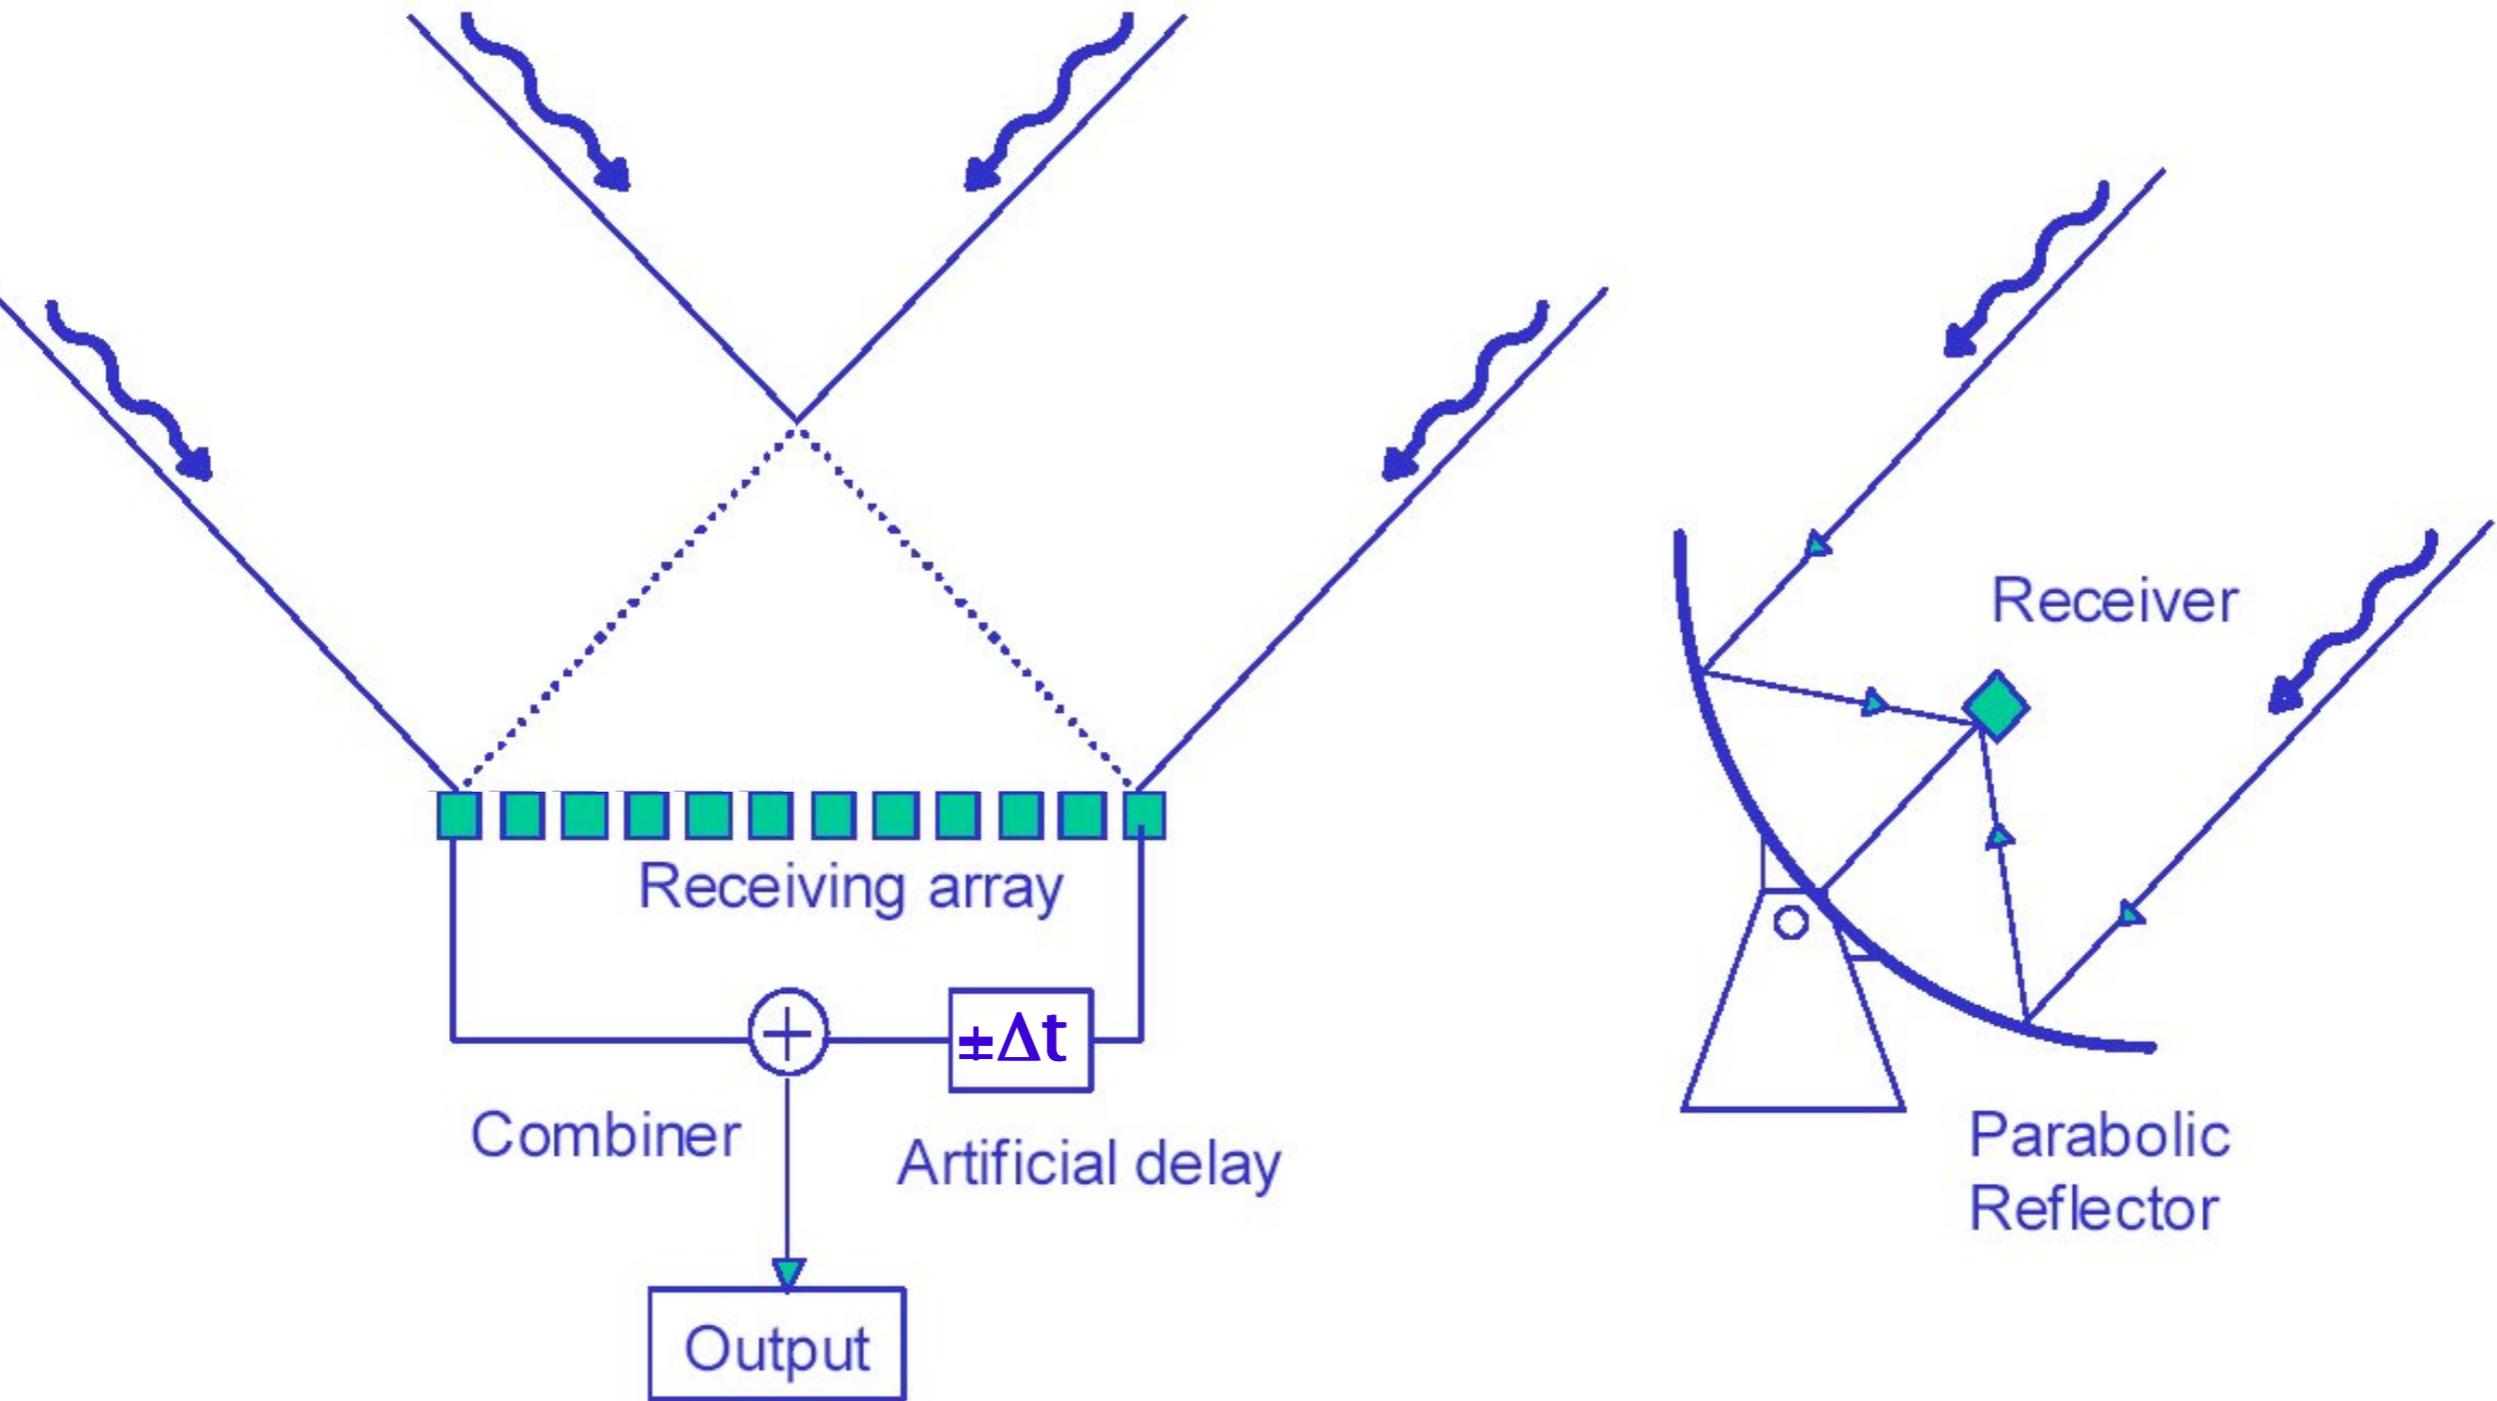

3+ Gbit/sec link

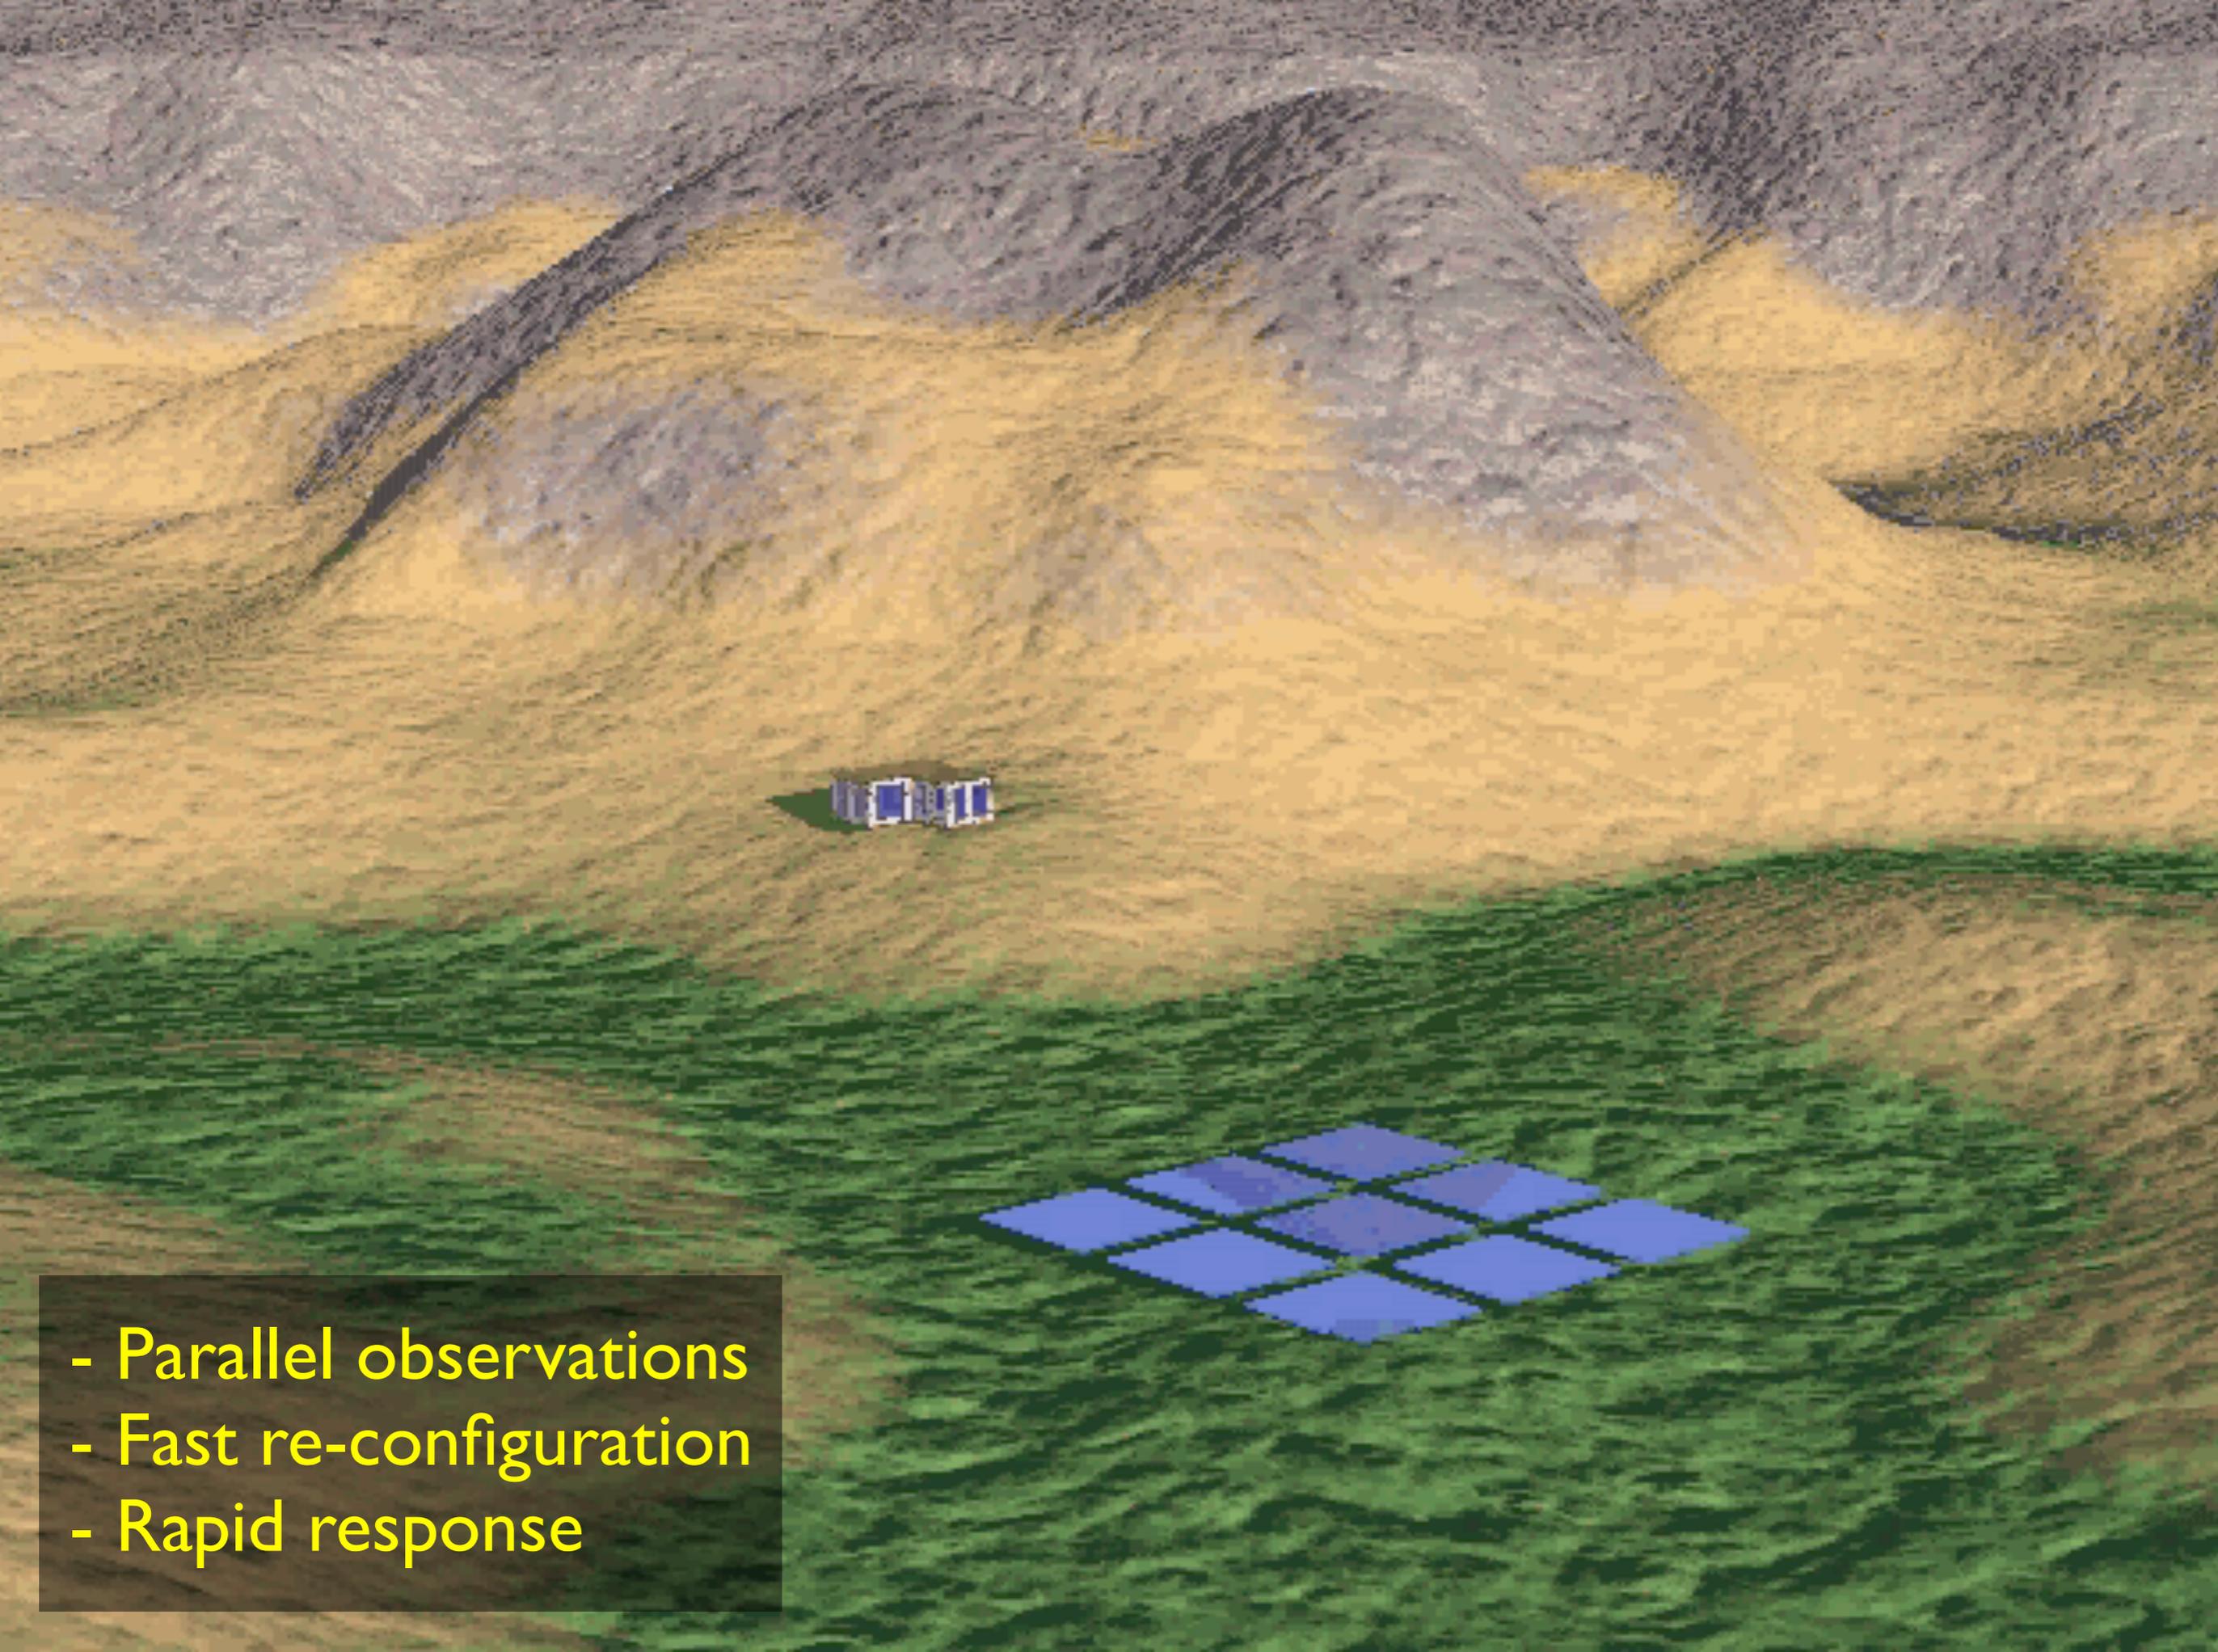

Superordinateur Blue Gene

Phased Array Detectors

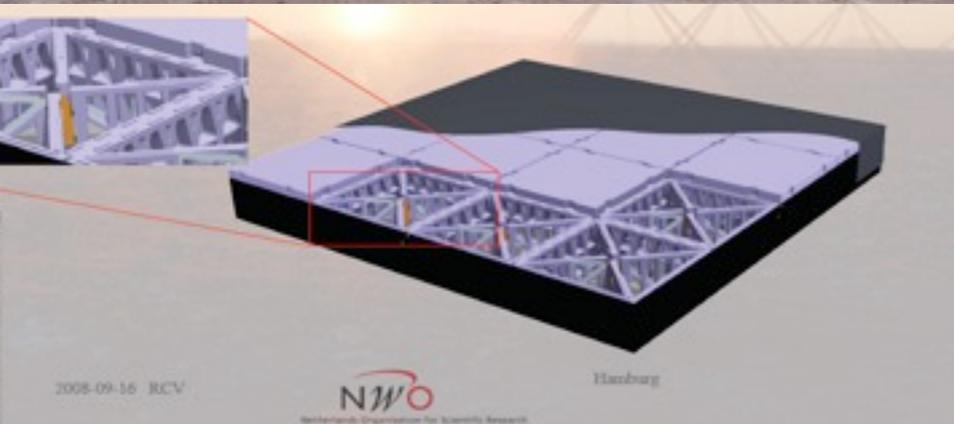

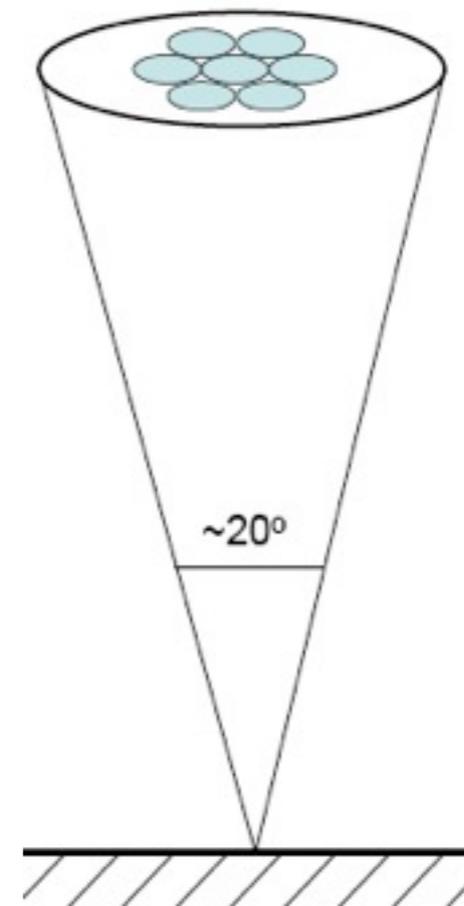

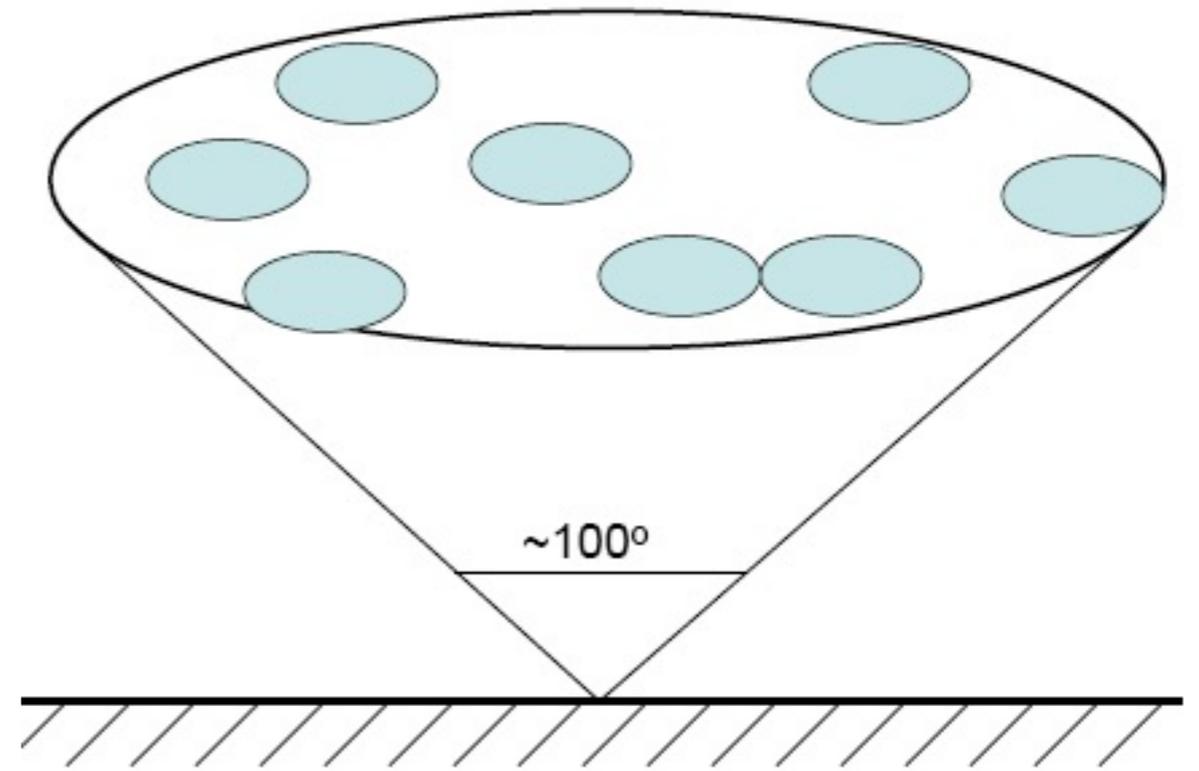

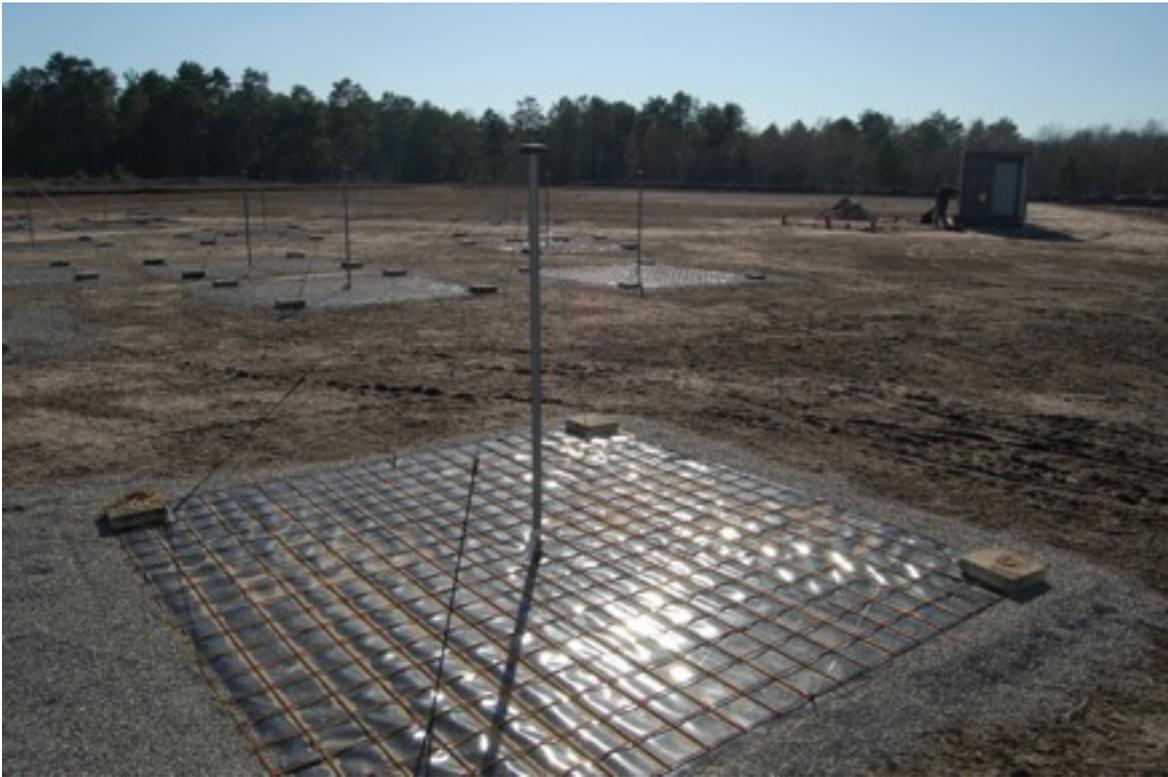

Electronic beam steering

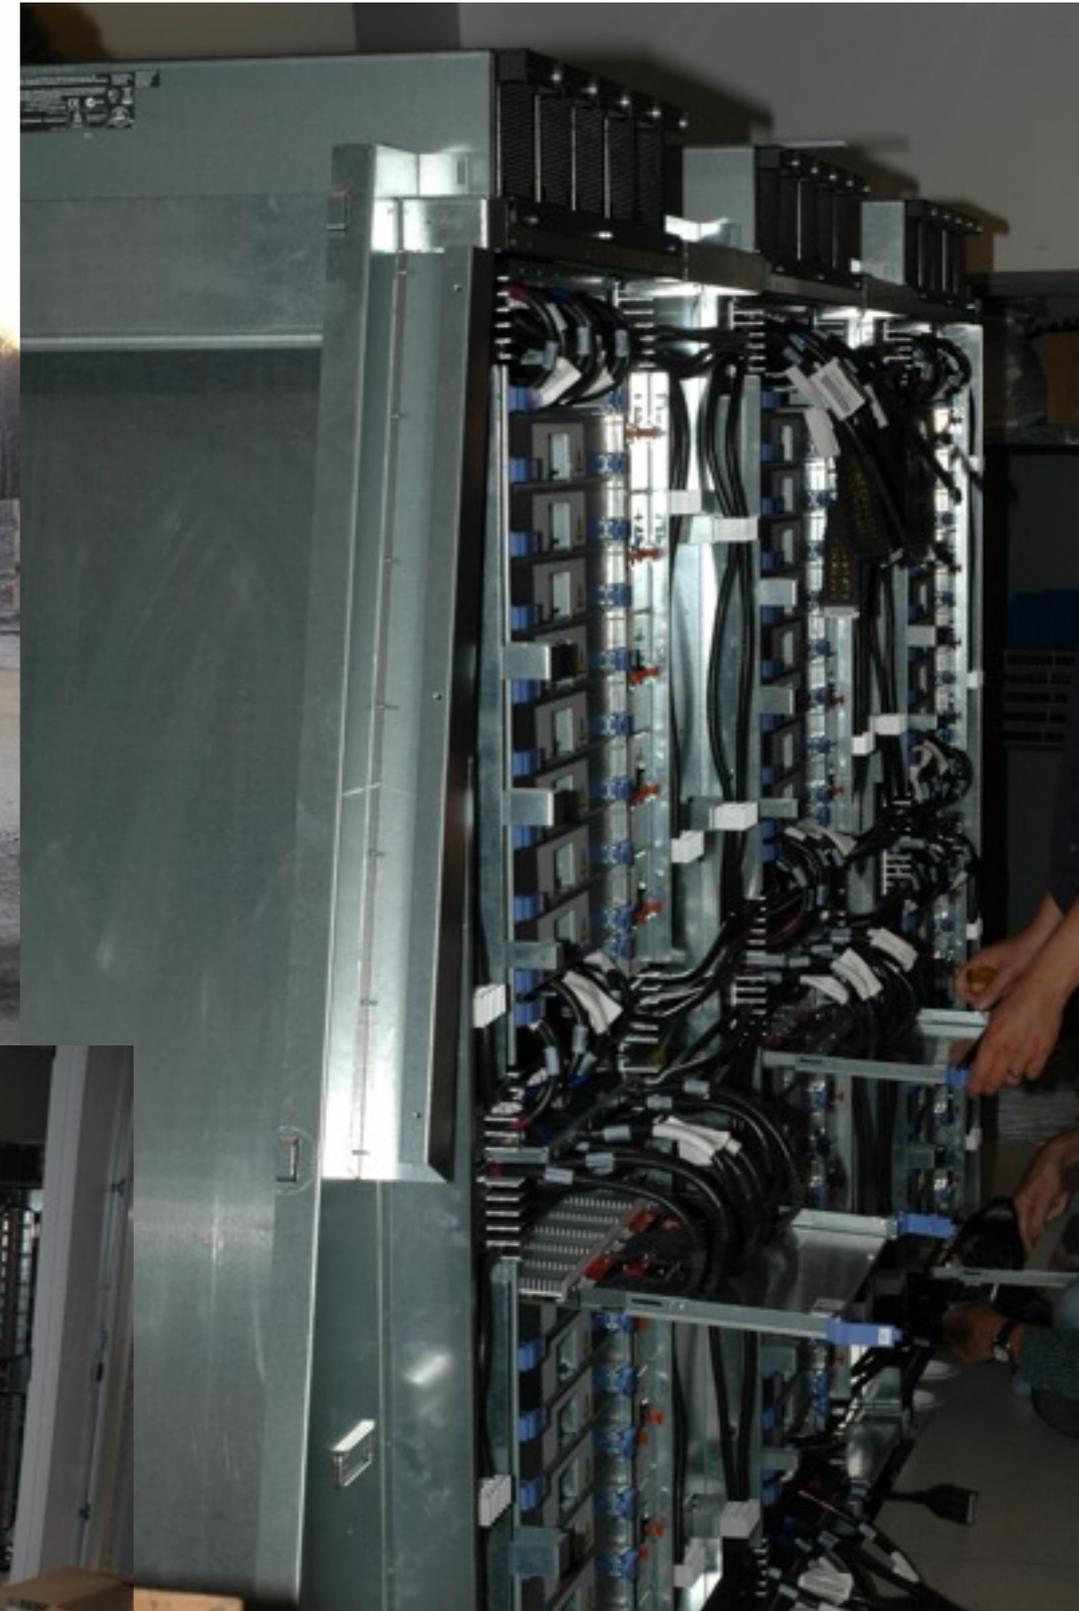

- Parallel observations
- Fast re-configuration
- Rapid response

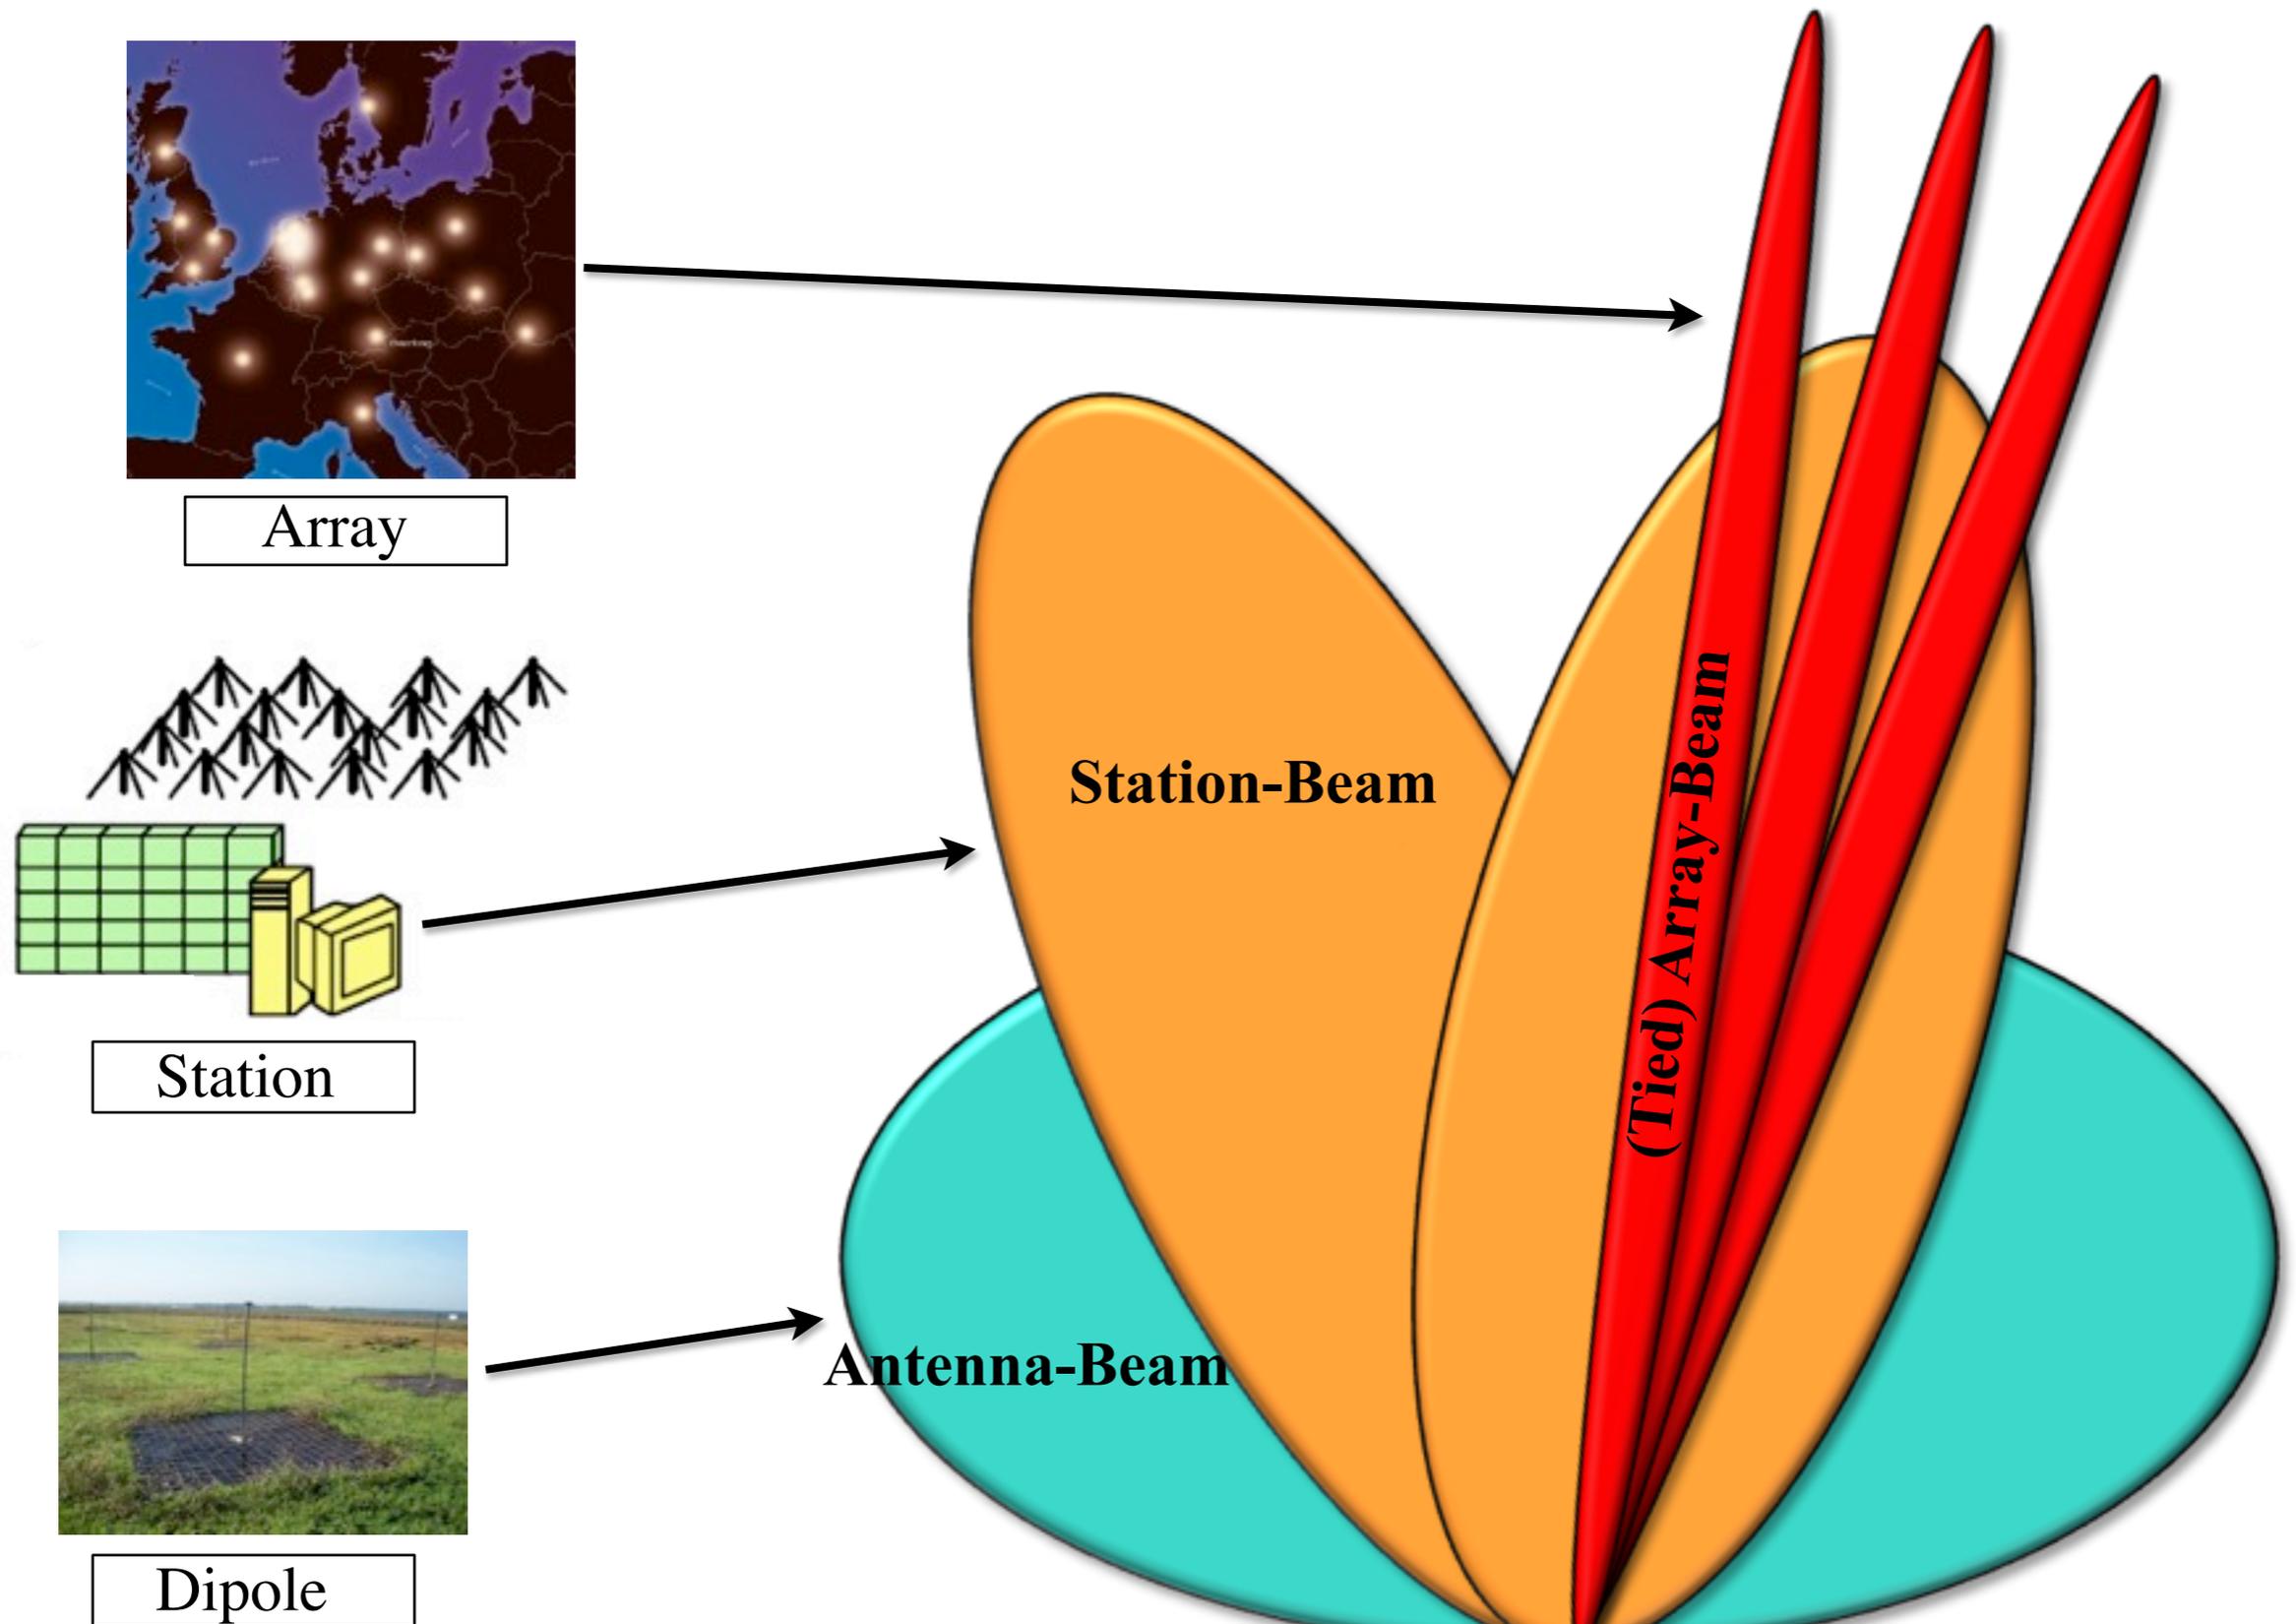

LBA & HBA antennas & FoV

FR606 Backends

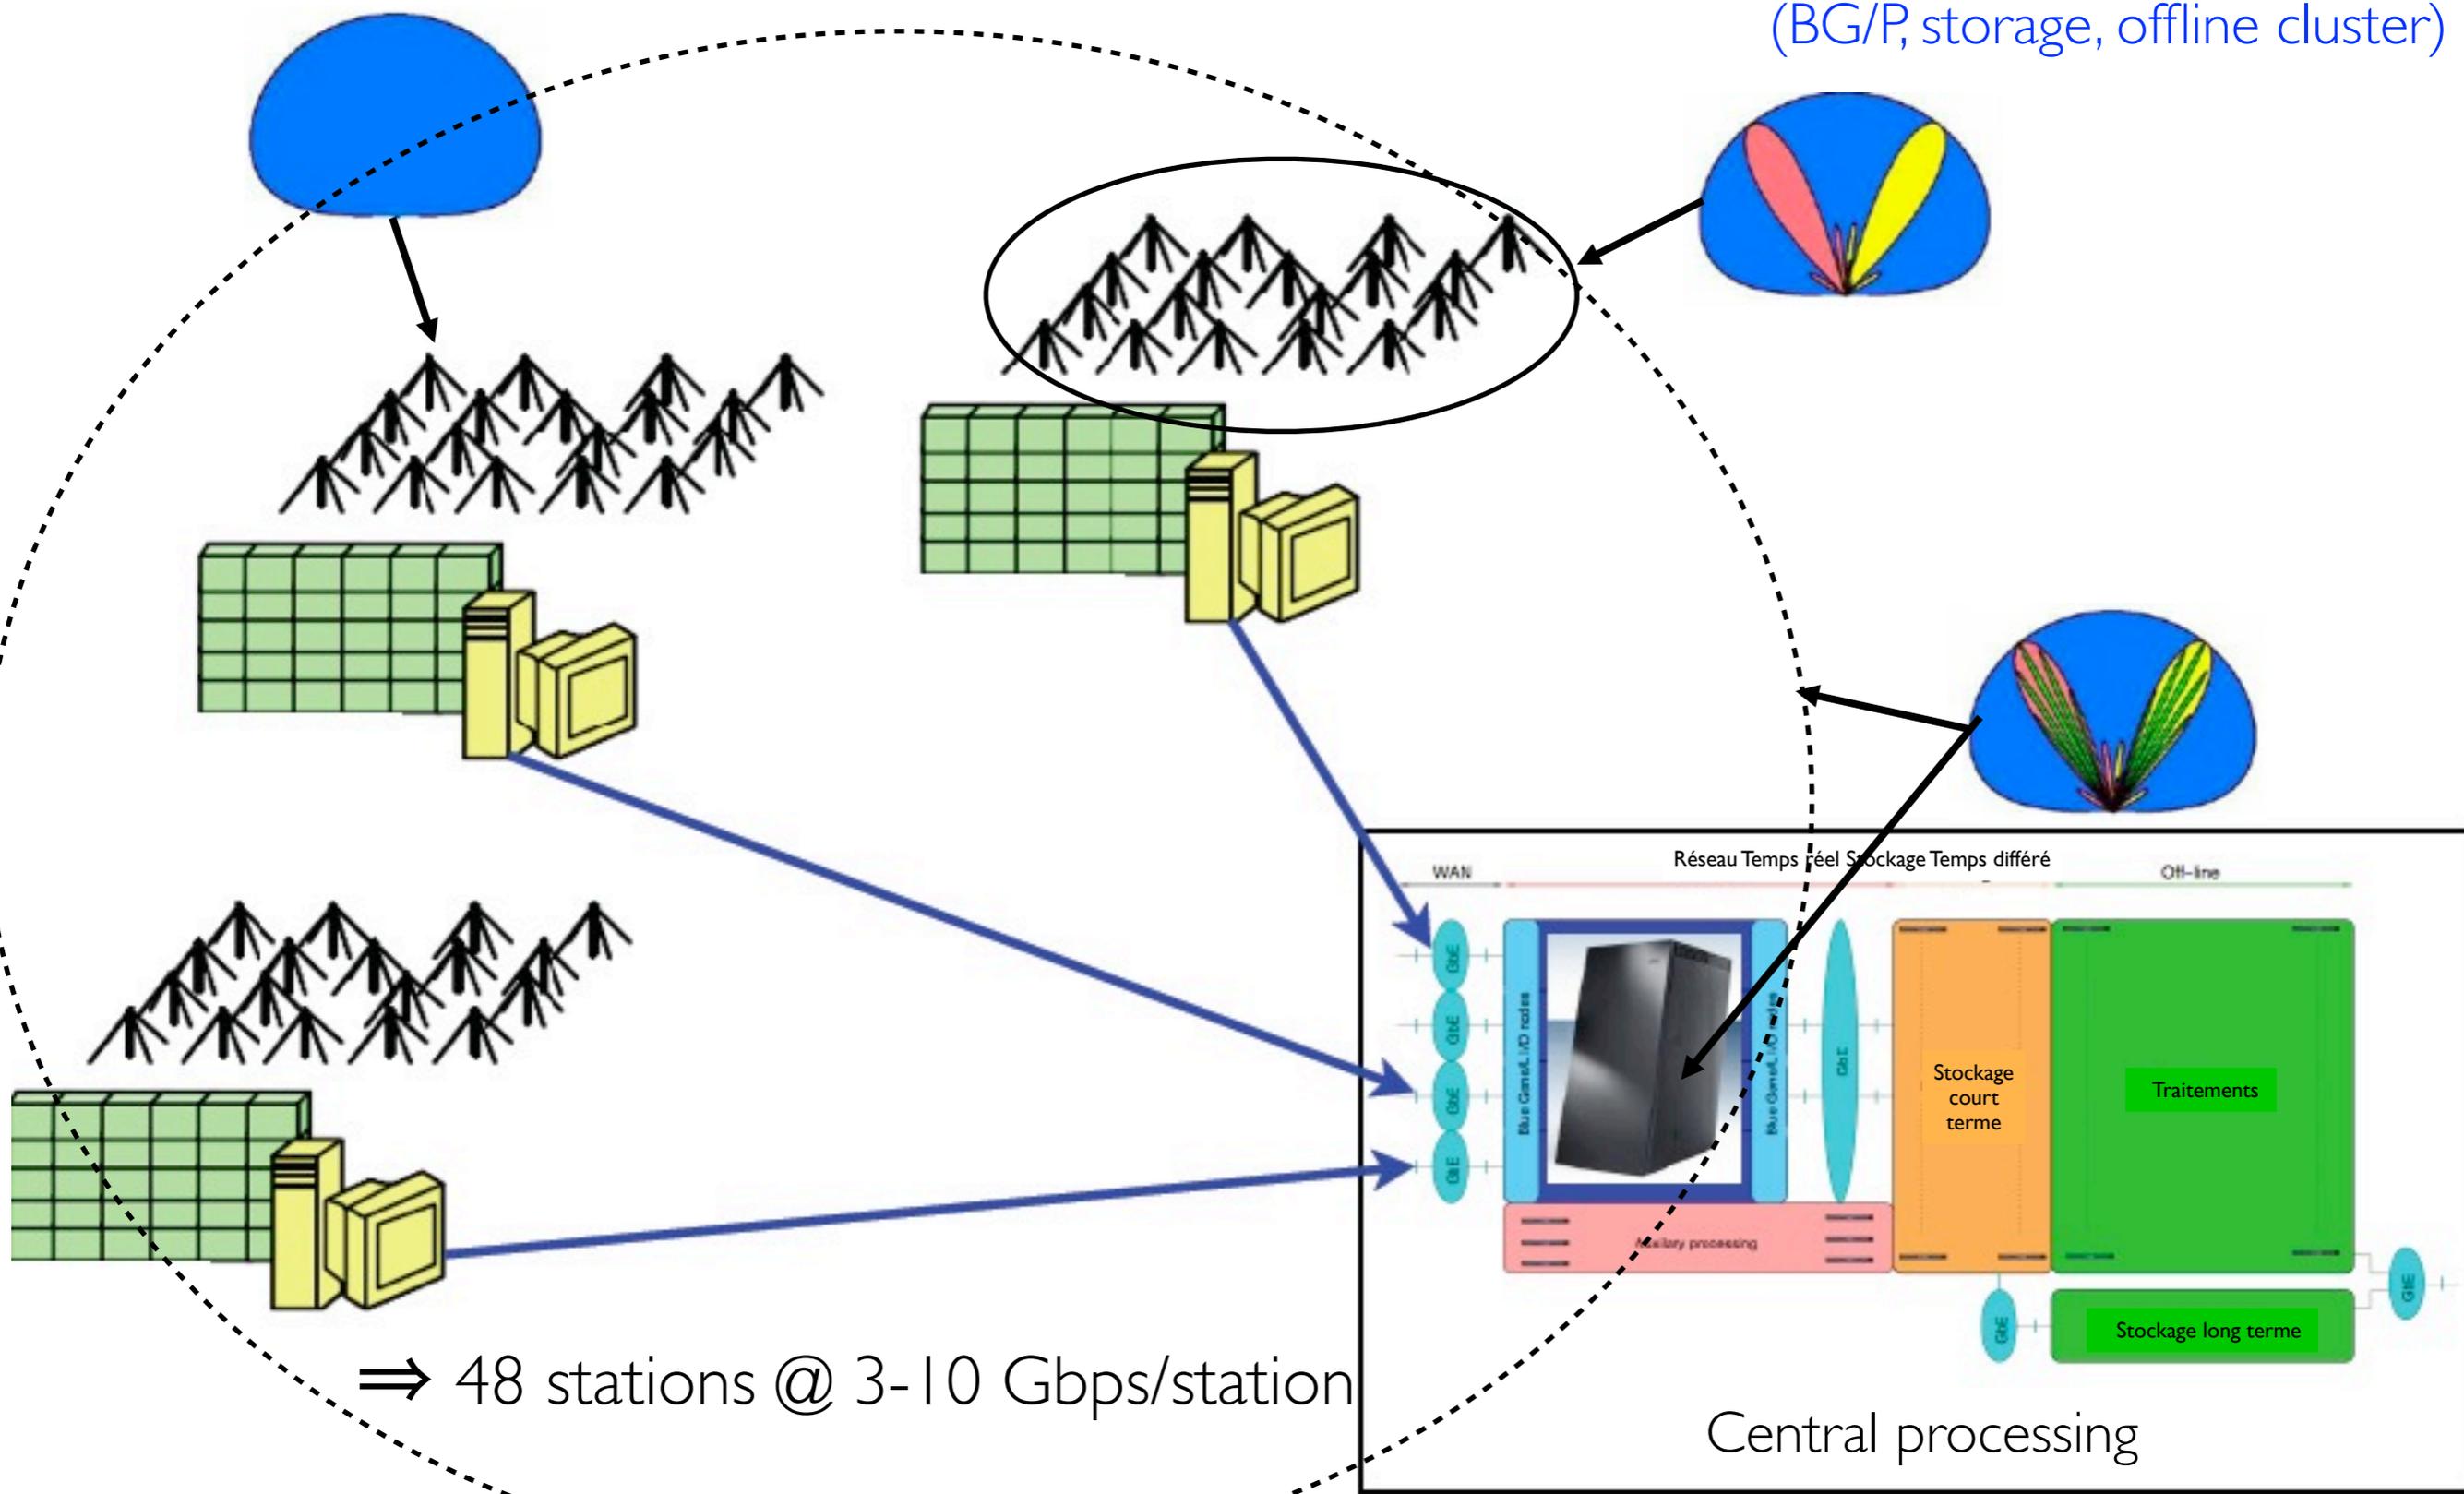

Digital beamforming

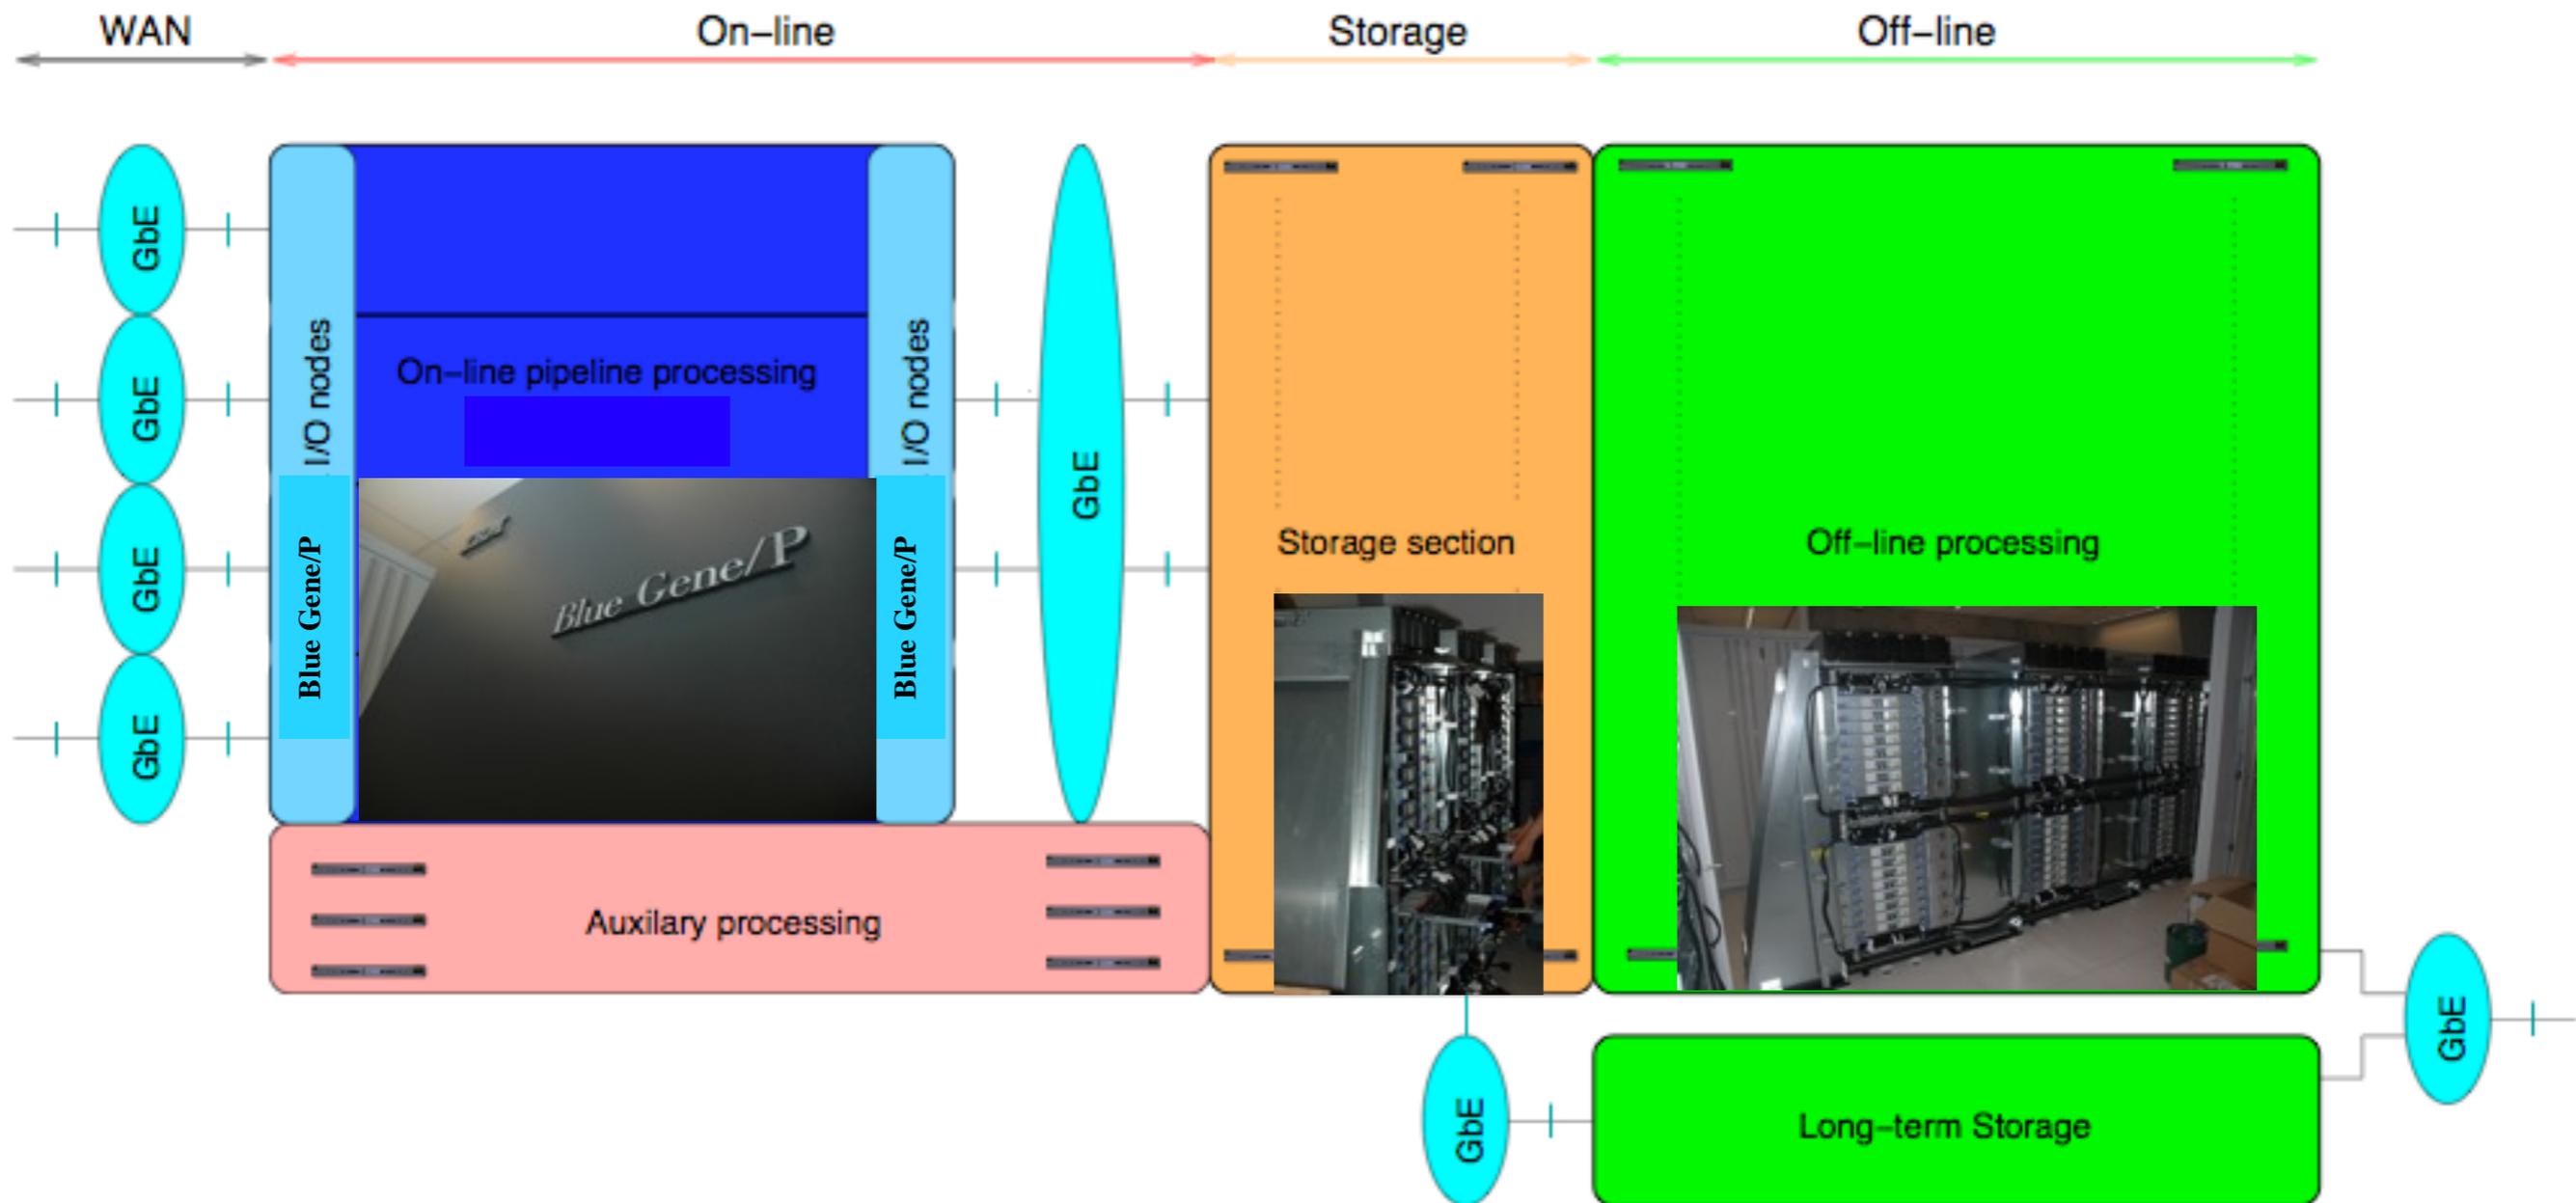

The LOFAR array

- Station level processing : amplification, digitization, filtering, beam-forming, transient ram buffers (TBB)
- Central processing : delay compensation, correlation or summation, calibration, science pipelines

(BG/P, storage, offline cluster)

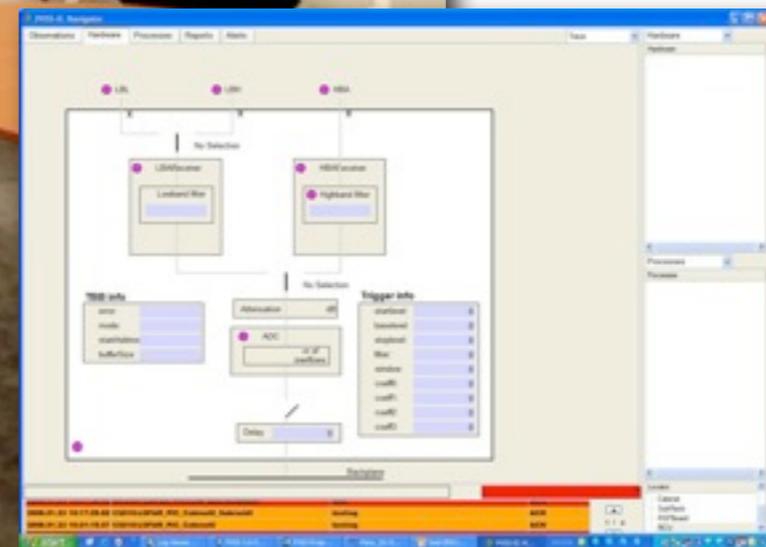

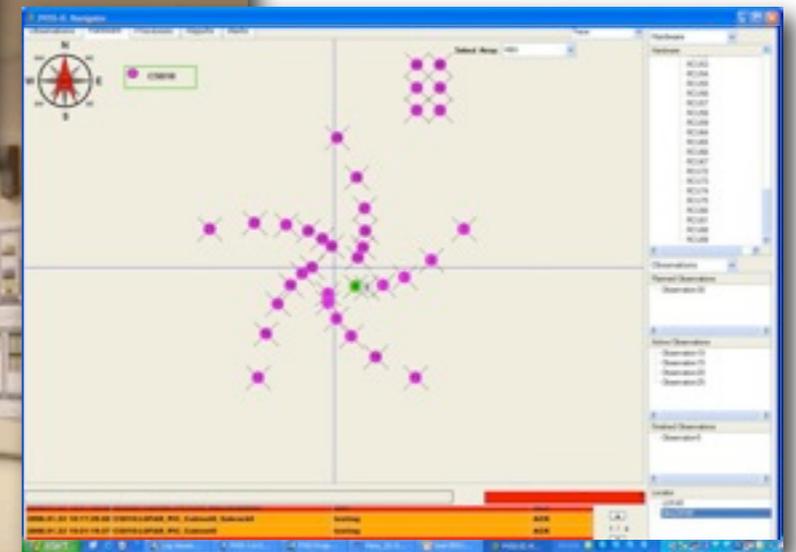

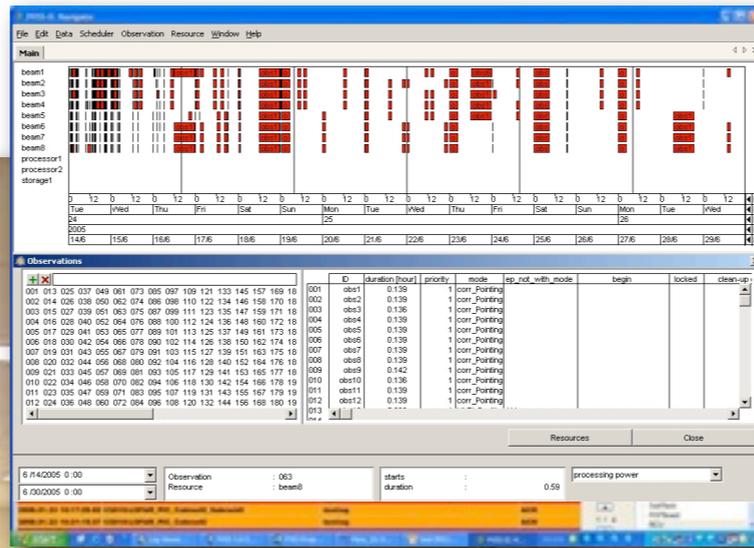

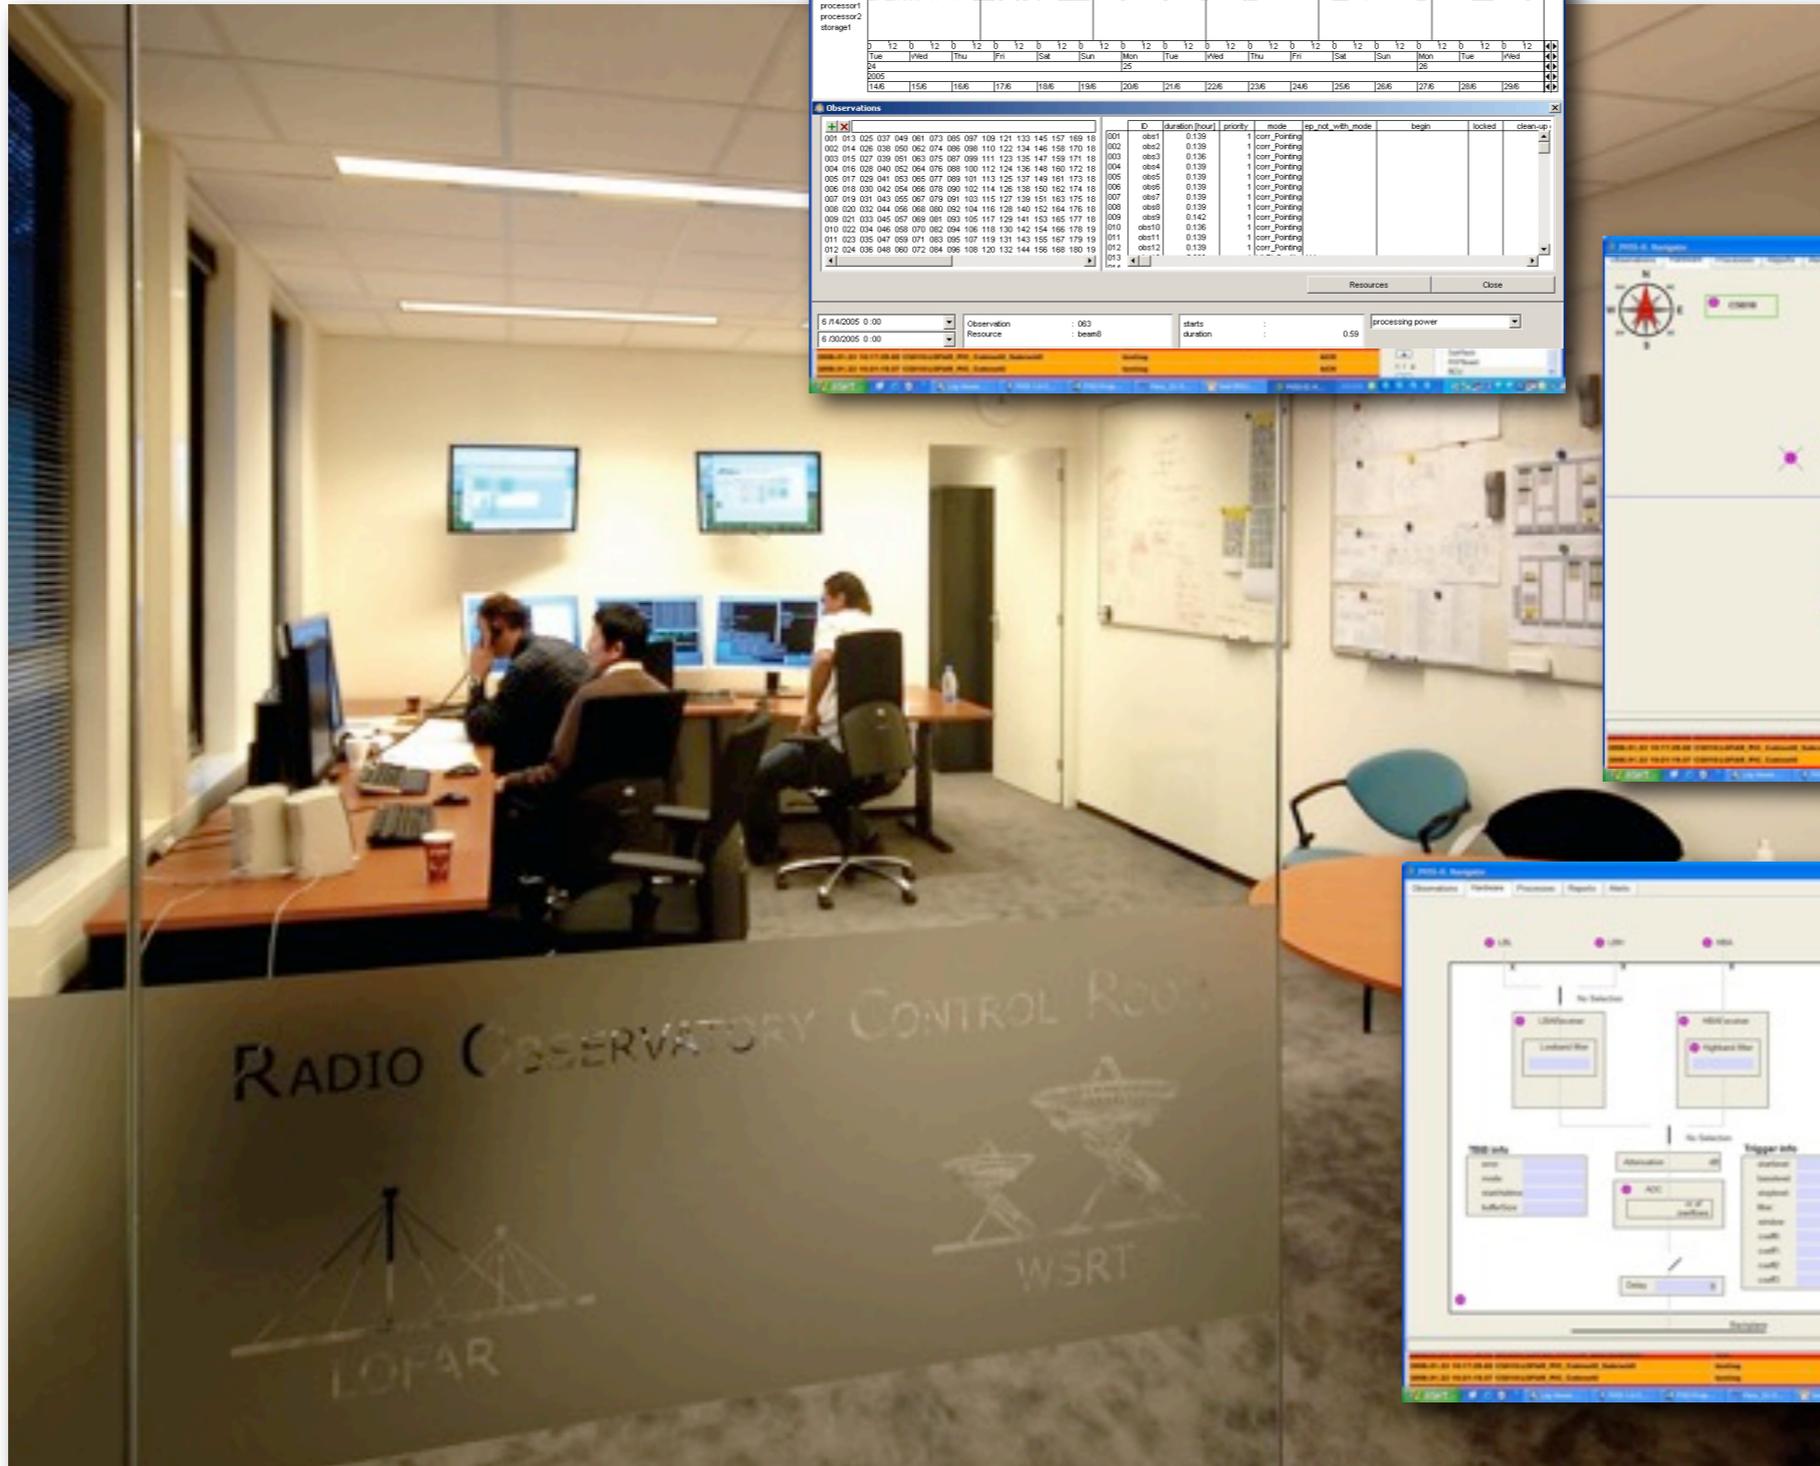

Central Processing

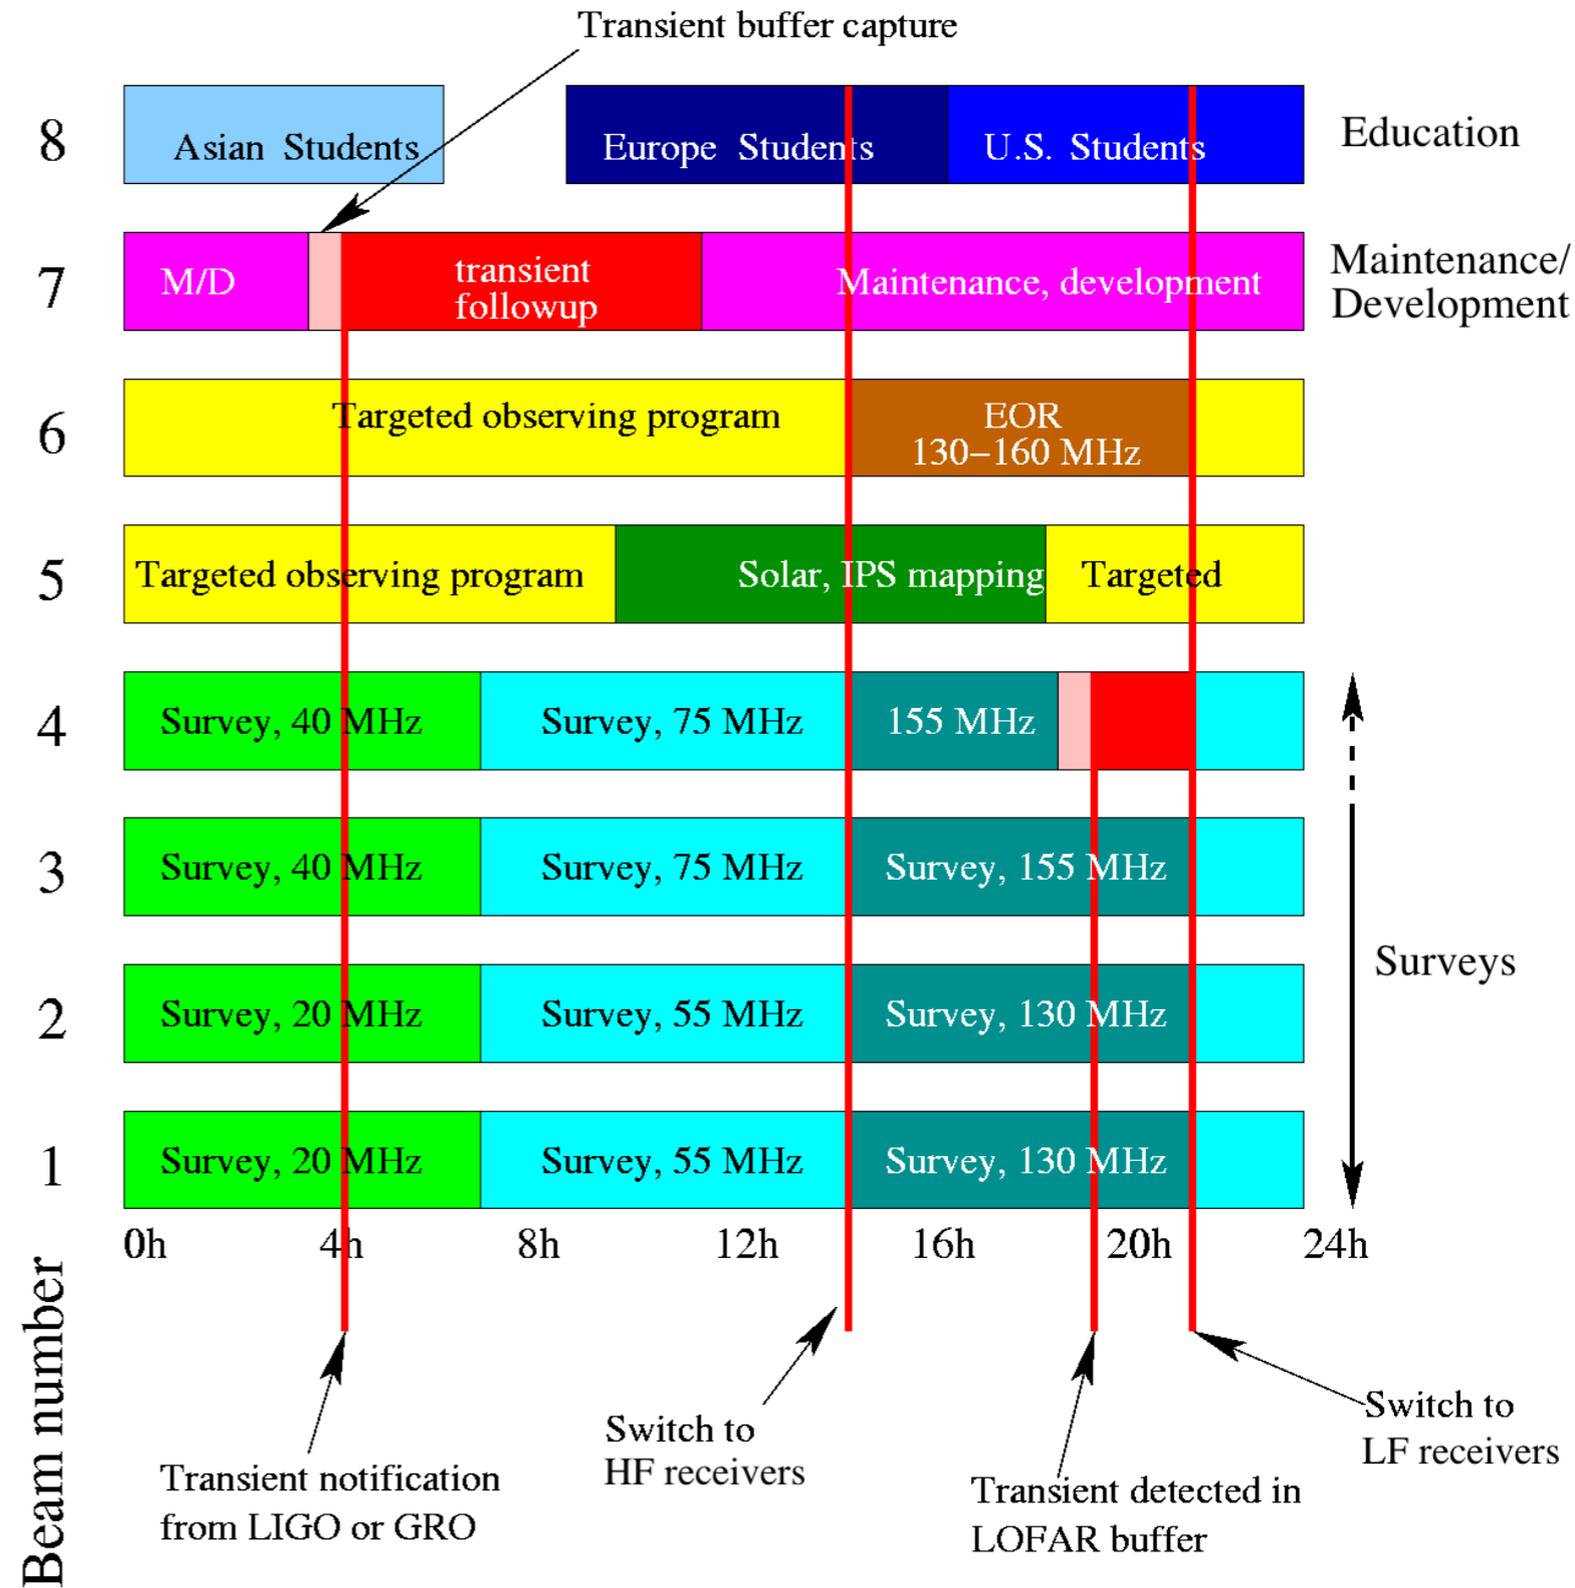

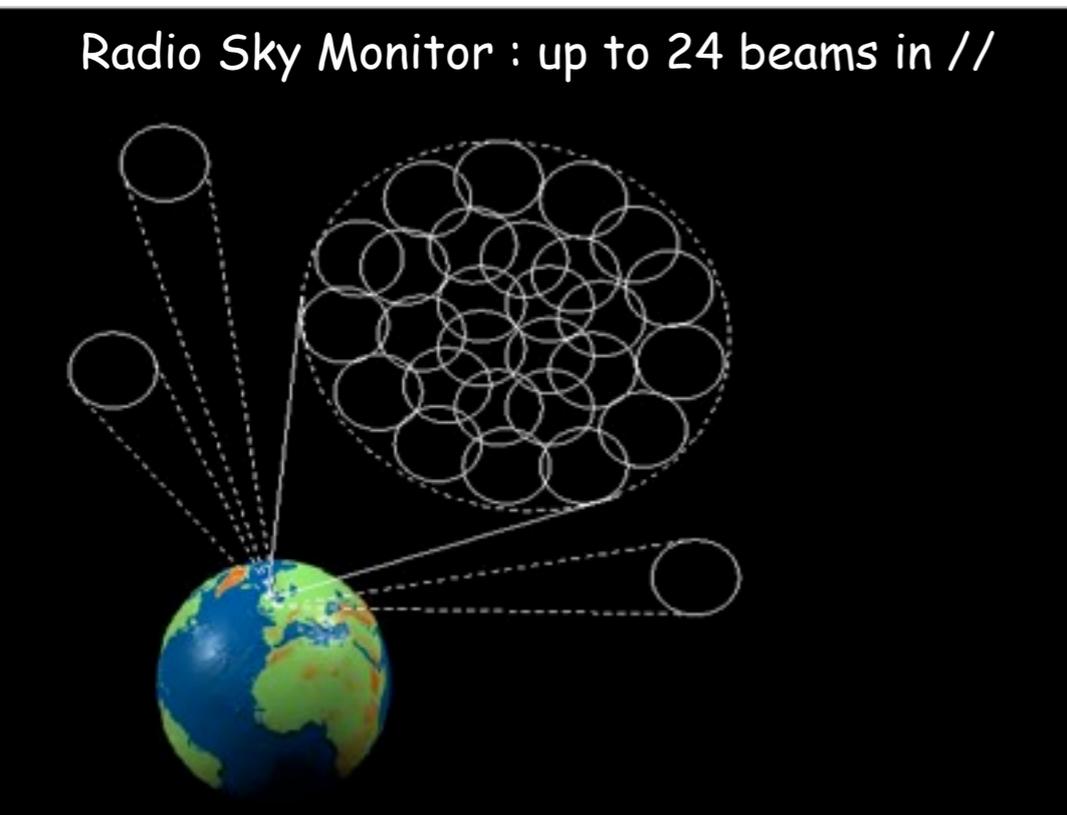

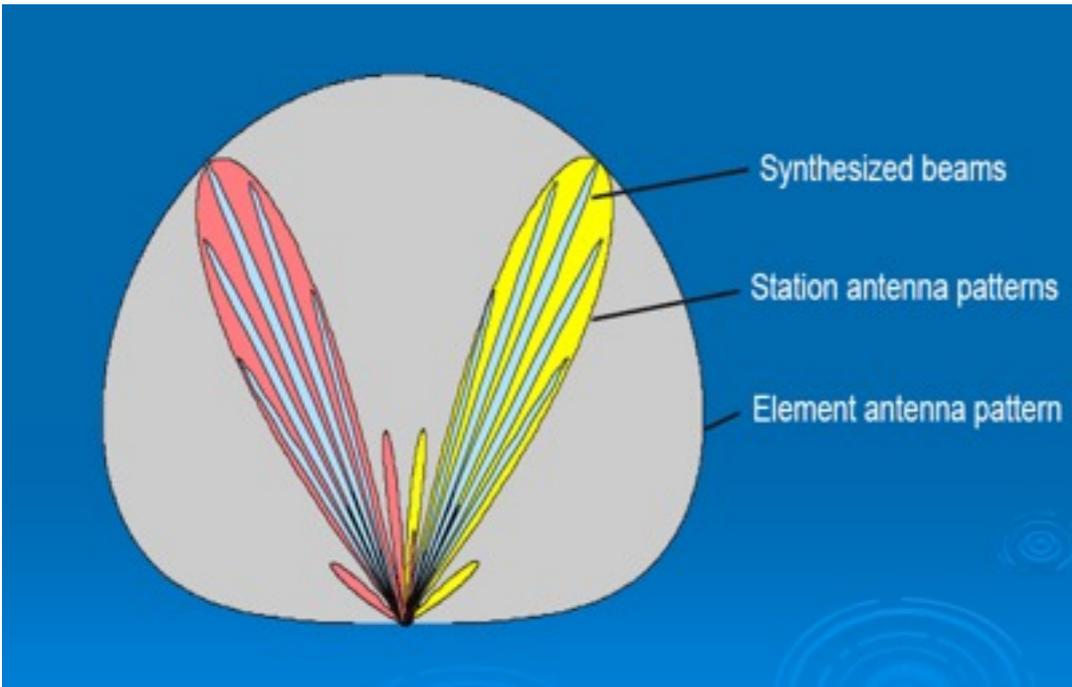

- BG/P : Data reception, transpose, correlation, beam-forming, de-dispersion, 45 TFLOPS
- Storage system : Short term storage of data, ~2 PByte, ~100Gbps I/O
- Offline cluster : Pipelines, data products, off-line analysis, ~20 TFLOPS

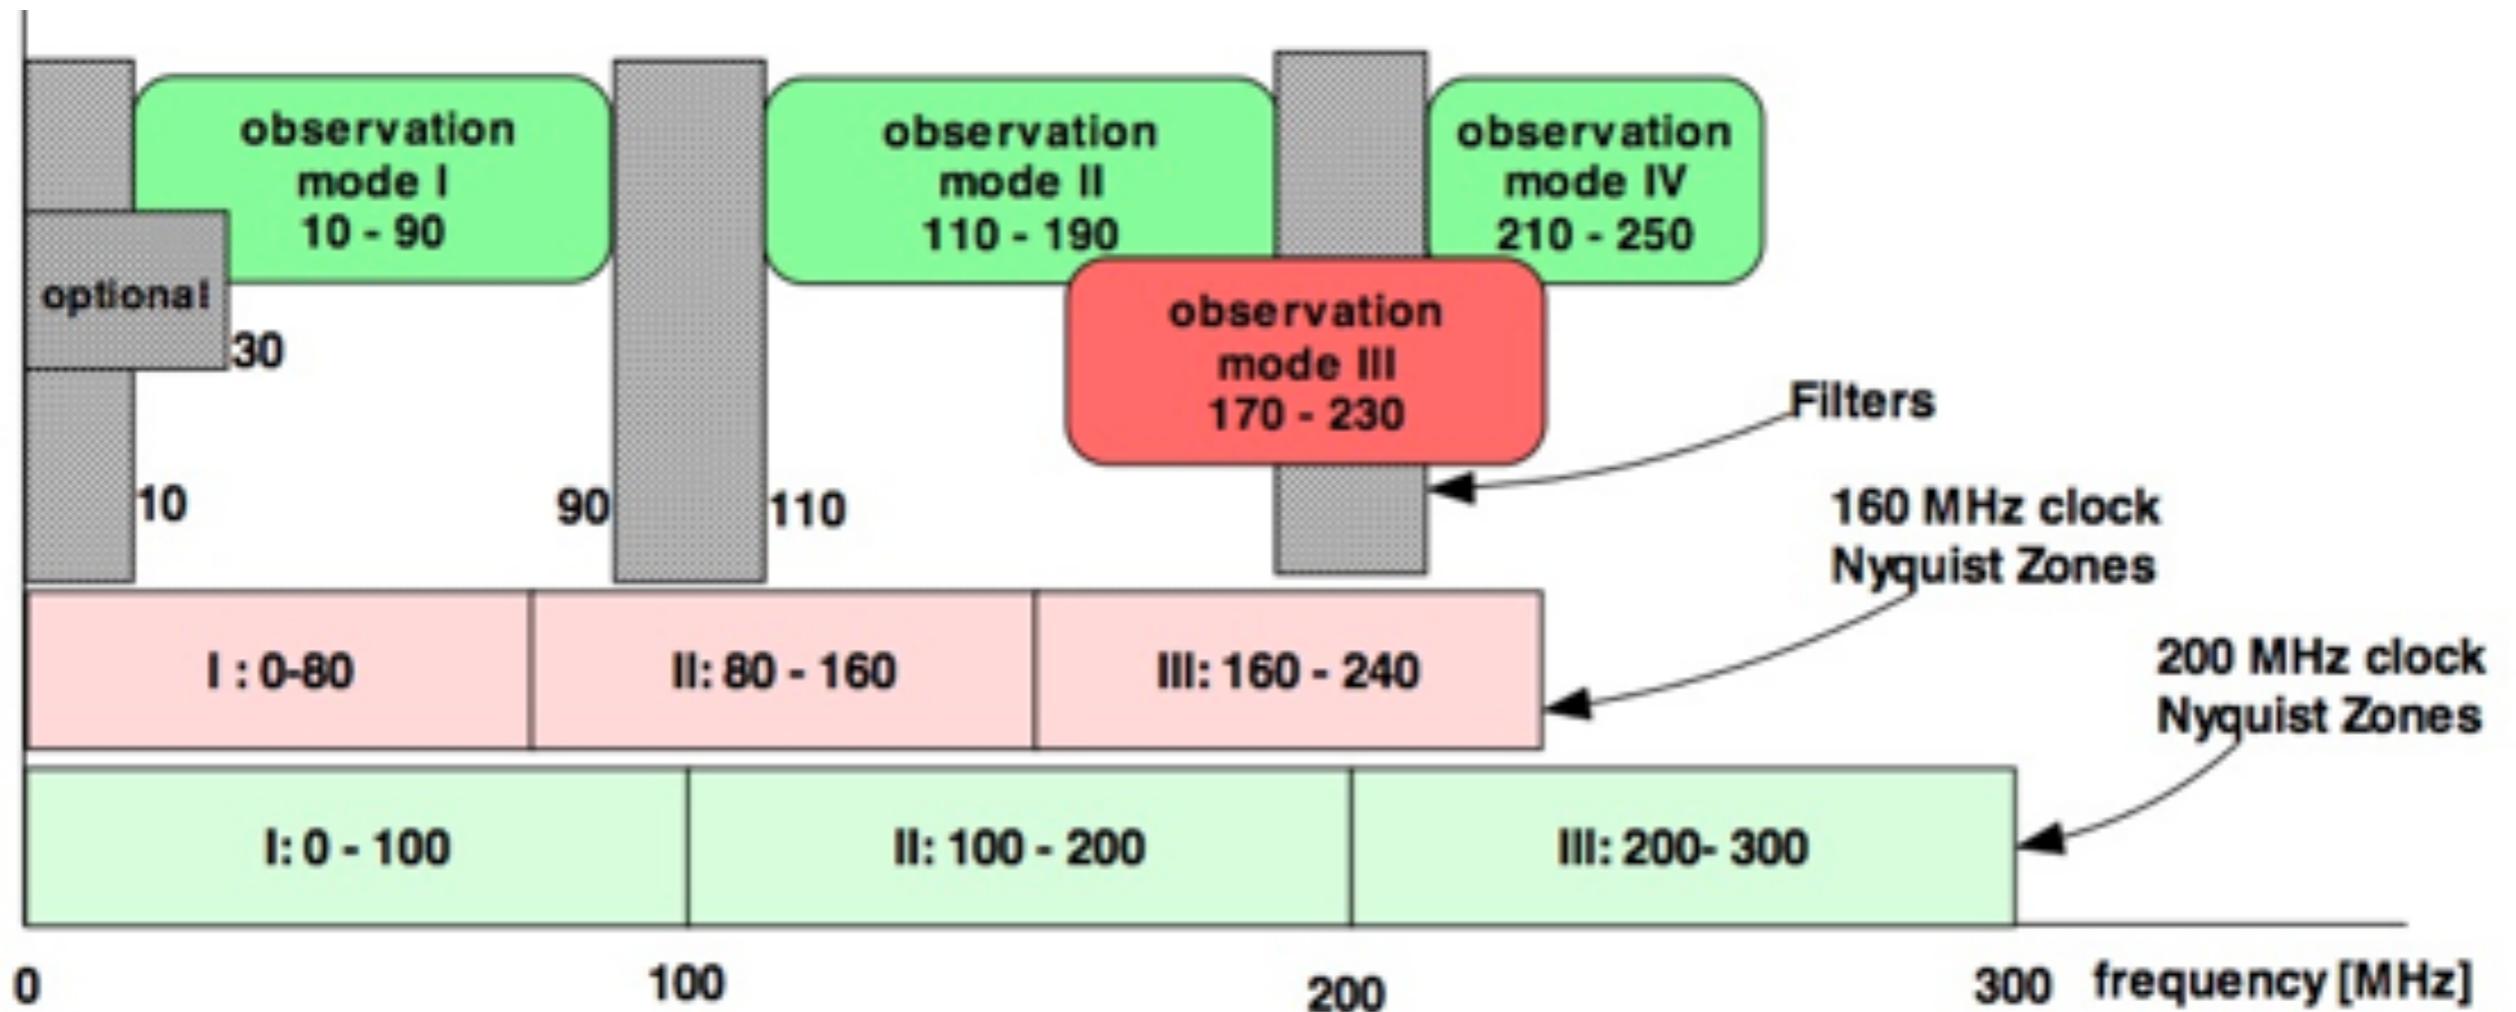

Remote Operation

Multi-beam Multi-programs telescope

Frequency ranges

Summary of technical characteristics

- European « Interferometer » of « Phased arrays »
- 24 stations «core» + 16 remote + 8 international
- Diameter ~100 km (NL) → 1500 km (Europe)
- Effective area ~ 100 000 m² ($\propto \lambda^2$)
- Frequency ranges = 30-80 & 110-250 MHz ($\lambda=1.2-10\text{m}$)
- Operation Modes = imaging, tied-array beams, waveform capture
- Resolution ~ 0.1 " - 10 " , large FoV ($\sim 10^\circ$)
- Sensitivity < mJy ($10^{-29} \text{ Wm}^{-2}\text{Hz}^{-1}$)
- Resolutions → 1 msec × 1 kHz, Full polarization
- RFI mitigation, ionospheric « adaptive optics »
- First Low-Frequency « all-purpose » spectro-imager
- 1st SKA precursor

LOFAR OBSERVING CAPABILITIES FOR ASTRONOMERS

LOFAR

LOFAR the Low Frequency Array is a next-generation electronically steered phased array radio telescope. LOFAR's capabilities are revolutionising the astronomical capabilities in the 10-240 MHz range. LOFAR, has been designed and constructed by ASTRON. Forty LOFAR stations are placed in the Netherlands, as well as 5 stations in the Germany (3) and one each in France, Sweden and the UK.

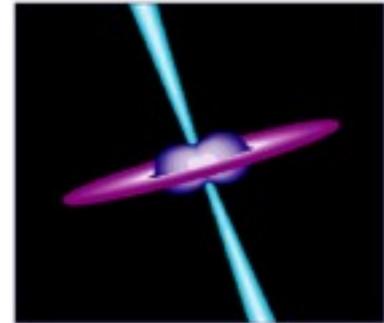

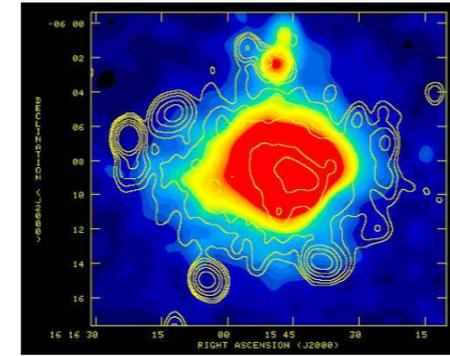

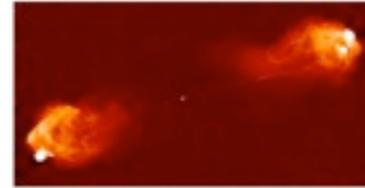

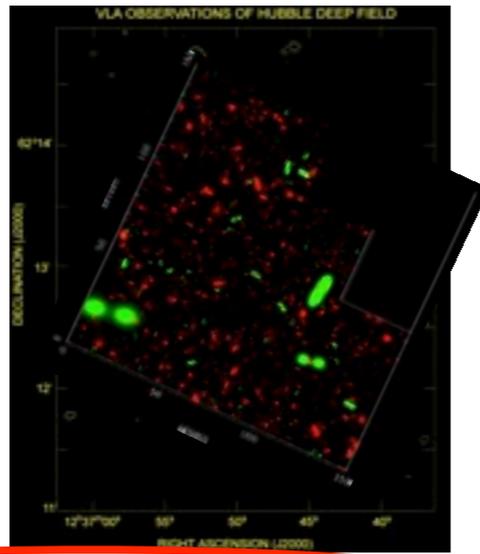

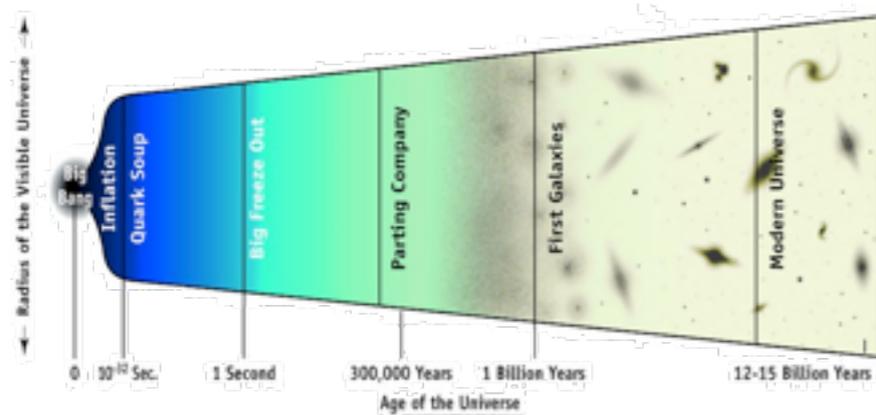

LOFAR is jointly operated by the International LOFAR Telescope (ILT) foundation, as an observatory open to the astronomical community.

LOFAR entered its first operational cycle in December 2012, following a period of commissioning.

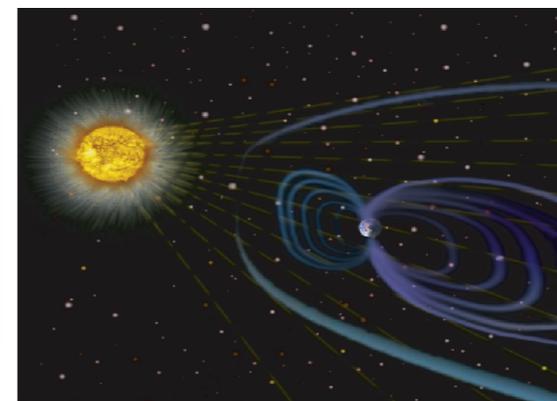

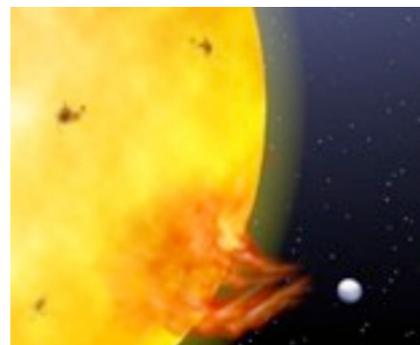

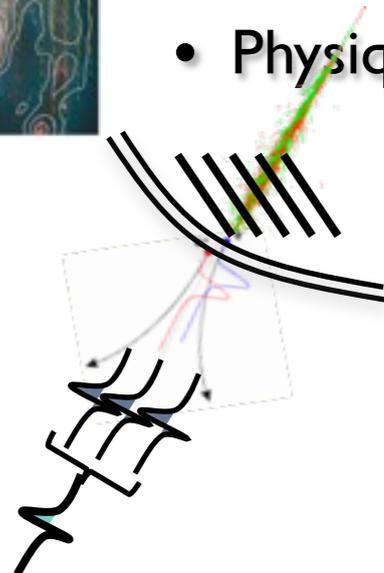

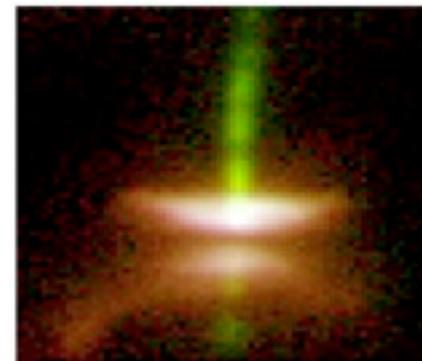

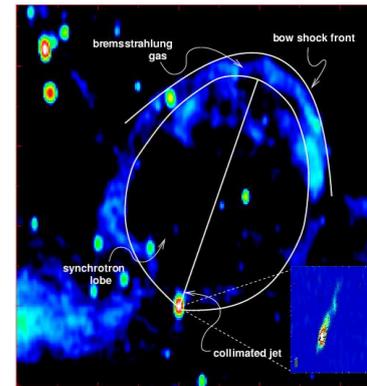

The following web pages describe the LOFAR's observing capabilities, major observing modes and analysis pipelines:

Instrument response

Wave Polarization

$$\mathbf{E} = \begin{bmatrix} E_x \\ E_y \end{bmatrix} = \begin{bmatrix} A_x e^{i(\omega t + \phi_x)} \\ A_y e^{i(\omega t + \phi_y)} \end{bmatrix} = e^{i\omega t} \begin{bmatrix} A_x e^{i\phi_x} \\ A_y e^{i\phi_y} \end{bmatrix}$$

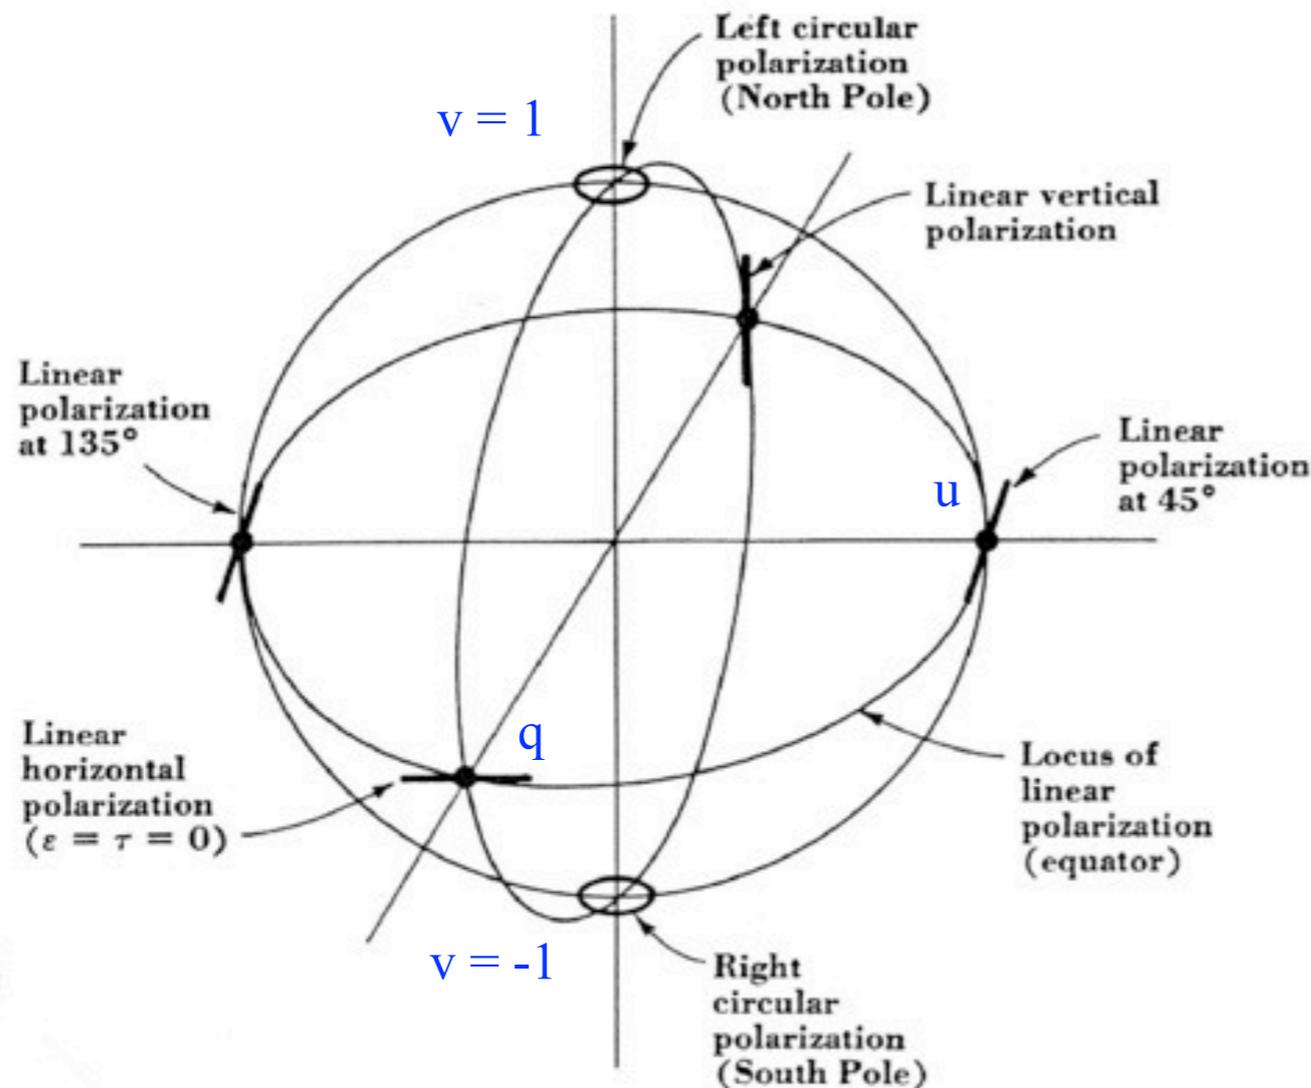

Stokes parameters : S (or I), Q, U, V
 normalized: $q=Q/S$, $u=U/S$, $v=V/S$

$$S = \langle A_x^2 + A_y^2 \rangle / 2Z_0$$

$$Q = \langle A_x^2 - A_y^2 \rangle / 2Z_0$$

$$U = \langle A_x A_y \cos(\phi_x - \phi_y) \rangle / Z_0$$

$$V = \langle A_x A_y \sin(\phi_x - \phi_y) \rangle / Z_0$$

Polarization at cardinal points of Poincaré sphere.

The Measurement Equation

Hamaker et al., 1996

$$\mathbf{E} = \begin{bmatrix} E_x \\ E_y \end{bmatrix} = \begin{bmatrix} A_x e^{i(\omega t + \phi_x)} \\ A_y e^{i(\omega t + \phi_y)} \end{bmatrix} = e^{i\omega t} \begin{bmatrix} A_x e^{i\phi_x} \\ A_y e^{i\phi_y} \end{bmatrix}$$

$$\mathbf{J} = \begin{bmatrix} A_x e^{i\phi_x} \\ A_y e^{i\phi_y} \end{bmatrix}$$

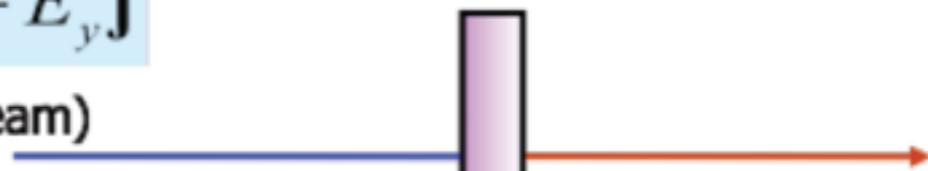

Jones vector

$$\mathbf{C} = \langle \mathbf{E} \mathbf{E}^t \rangle |_{\Delta t} \gg 1/v = \begin{bmatrix} \langle E_x E_x^* \rangle & \langle E_x E_y^* \rangle \\ \langle E_y E_x^* \rangle & \langle E_y E_y^* \rangle \end{bmatrix} = \frac{1}{2} \begin{bmatrix} S+Q & U+iV \\ U-iV & S-Q \end{bmatrix}$$

Coherency matrix

$$\mathbf{J} = E_x \mathbf{i} + E_y \mathbf{j}$$

(Incident beam)

Optical device
M

$$\mathbf{J}' = E'_x \mathbf{i} + E'_y \mathbf{j}$$

(Emergent beam)

$$\begin{bmatrix} \Delta \\ \Delta \end{bmatrix} = \begin{bmatrix} \diamond & \diamond \\ \diamond & \diamond \end{bmatrix} \begin{bmatrix} \times \\ \times \end{bmatrix}$$

Jones vector (emergent light) Jones matrix (optical element) Jones vector (light source)

Application to interferometric imaging

Bregman et al., 1996, Sault et al., 1996

Measured visibility : $\mathbf{V} = \mathbf{J} \mathbf{E} = (V_x, V_y)$ = complex voltages from each polarized antenna element

Visibility matrix for each interferometer baseline :

$$\mathbf{V}_{ij} = \langle V_i {}^tV_j^* \rangle = \begin{bmatrix} \langle V_{ix} V_{jx}^* \rangle & \langle V_{ix} V_{jy}^* \rangle \\ \langle V_{iy} V_{jx}^* \rangle & \langle V_{iy} V_{jy}^* \rangle \end{bmatrix} = \langle \mathbf{J}_i \mathbf{E} {}^t(\mathbf{J}_j \mathbf{E})^* \rangle = \mathbf{J}_i \langle \mathbf{E} {}^t\mathbf{E}^* \rangle {}^t\mathbf{J}_j^* = \mathbf{J}_i \mathbf{C} {}^t\mathbf{J}_j^*$$

Signal transformations : $\mathbf{J}_i = \mathbf{B}_i \mathbf{G}_i \mathbf{D}_i \mathbf{E}_i \mathbf{P}_i \mathbf{T}_i \mathbf{F}_i$

$$V_{ij} = \sum_{\text{sky}} \mathbf{B}_i \mathbf{G}_i \mathbf{D}_i \mathbf{E}_i \mathbf{P}_i \mathbf{T}_i \mathbf{F}_i \frac{1}{2} \begin{bmatrix} S+Q & U+iV \\ U-iV & S-Q \end{bmatrix} {}^t\mathbf{F}_j^* {}^t\mathbf{T}_j^* {}^t\mathbf{P}_j^* {}^t\mathbf{E}_j^* {}^t\mathbf{D}_j^* {}^t\mathbf{G}_j^* {}^t\mathbf{B}_j^* + n$$

$$V_{ij} = \mathbf{J}_i \mathbf{C} {}^t\mathbf{J}_j^* + n$$

- F = ionospheric Faraday rotation
- $(T = \text{tropospheric effects})$
- P = parallactic angle
- E = antenna voltage pattern
- D = polarization leakage
- G = electronic gain
- B = bandpass response

(Self)-Calibration:

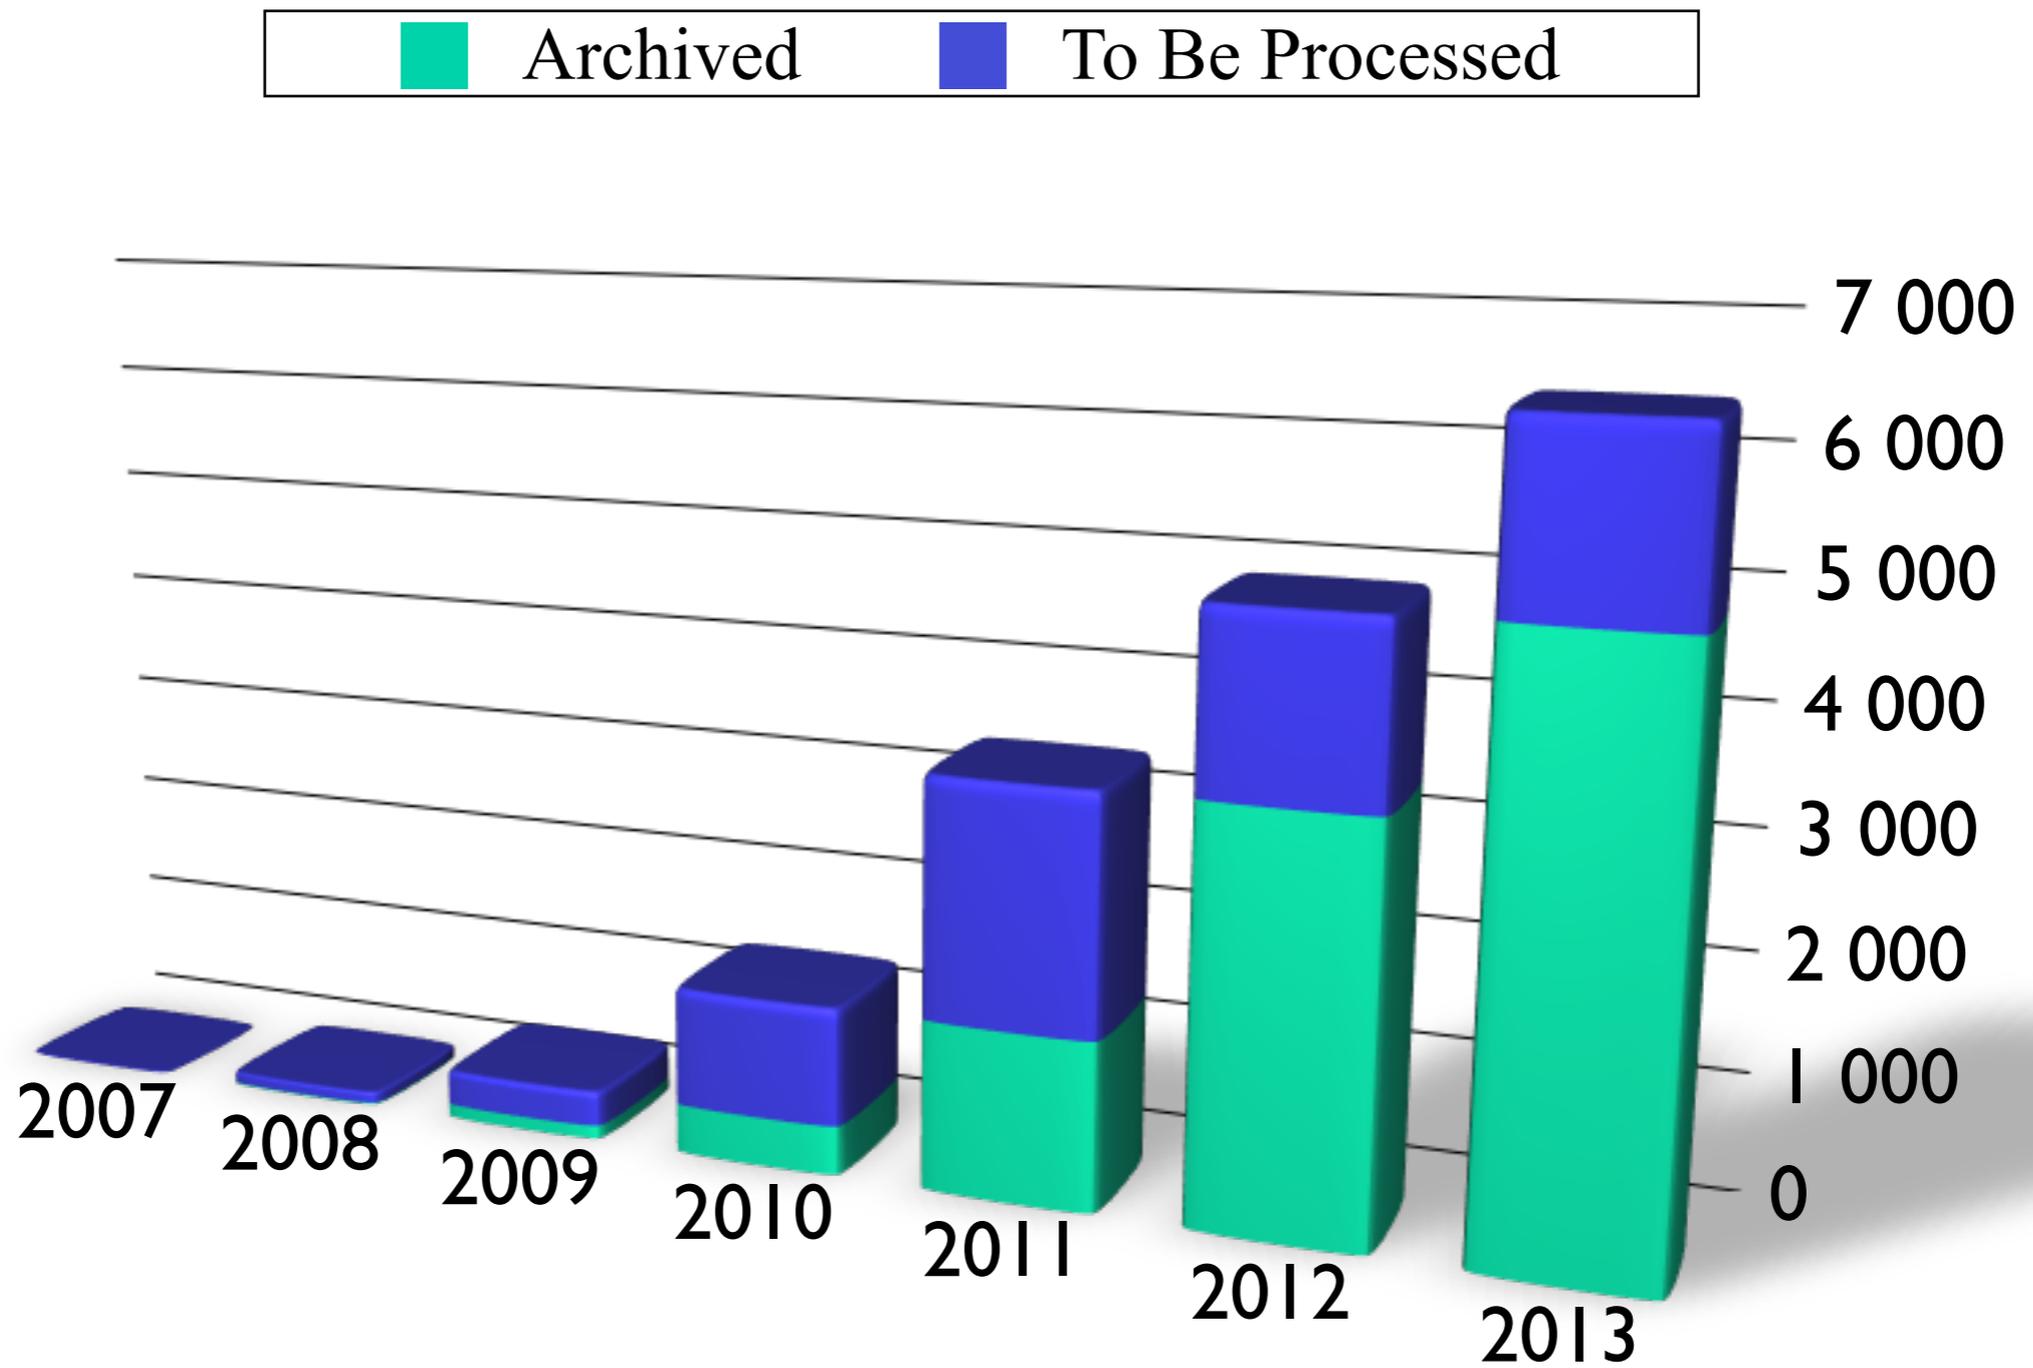

$$\text{Sky Model : } \sum_{\text{sky}} \mathbf{C} \Rightarrow V_{ij\text{-model}}$$

$$\text{Residuals : } V_{ij\text{-measured}} - V_{ij\text{-model}}$$

$$\text{Corrected residuals : } \mathbf{J}_i^{-1} (V_{ij\text{-measured}} - V_{ij\text{-model}}) {}^t\mathbf{J}_j^{-1*} \Rightarrow \text{minimize, iterate}$$

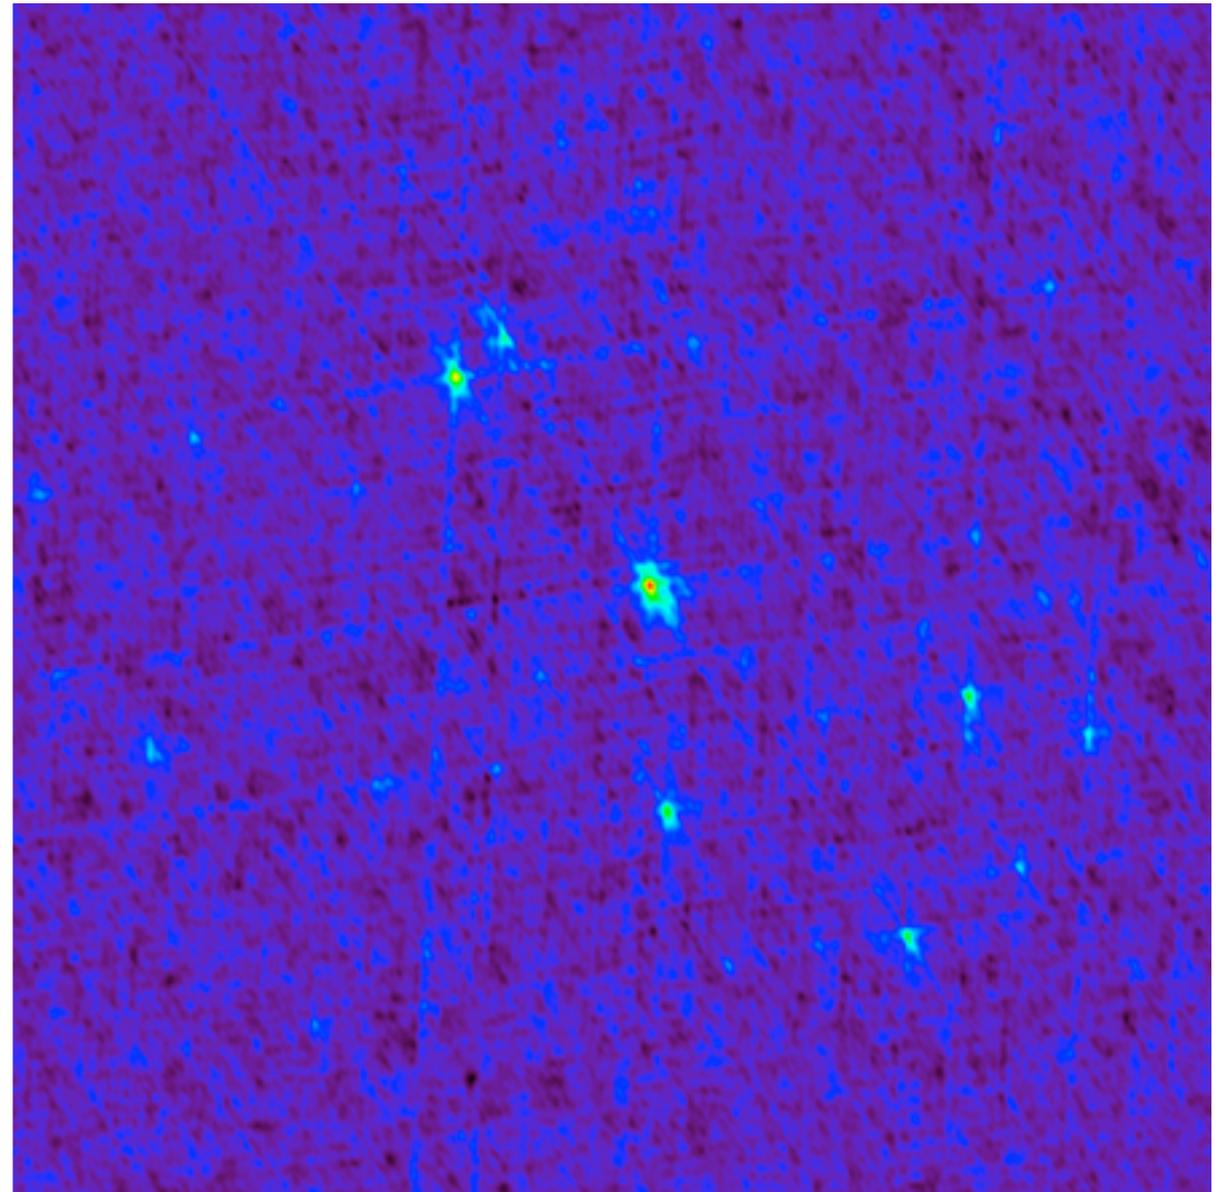

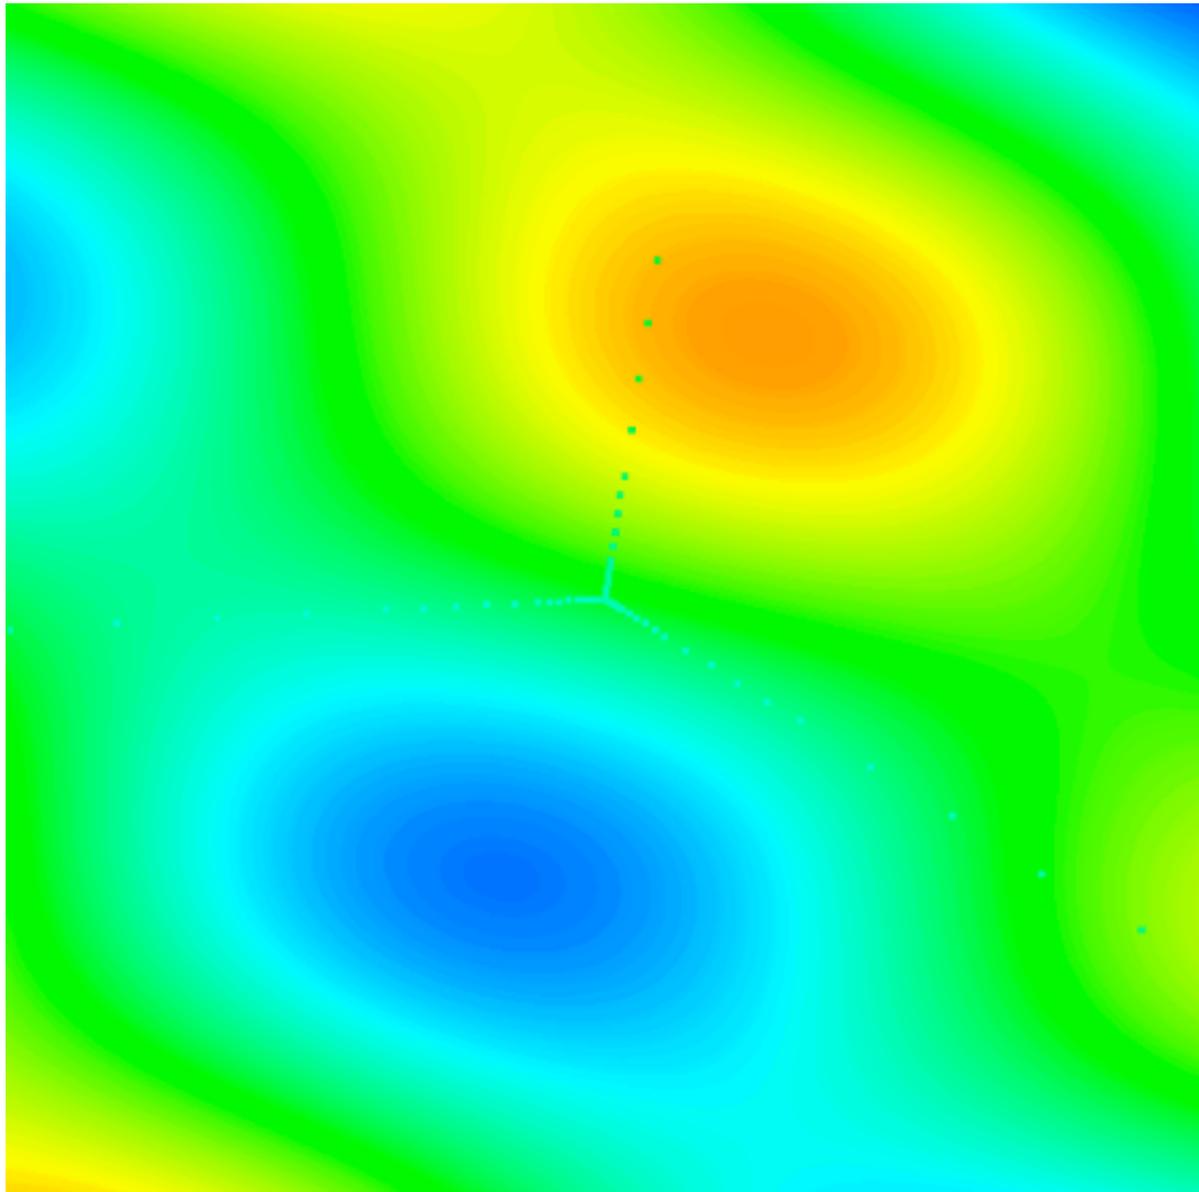

(computationally expensive)

LOFAR archive growth

Estimated growth rate ~ 2.5 Pb/yr

Modelling the ionosphere

Need of many sources / beam for proper calibration

The AWI Imager

Applying full polarization A-Projection to very wide field of view instruments: An imager for LOFAR

Tasse et al., 2013

C. Tasse^{1,2,3}, B. van der Tol⁴, J. van Zwieten⁵, Ger van Diepen⁵, and S. Bhatnagar⁶

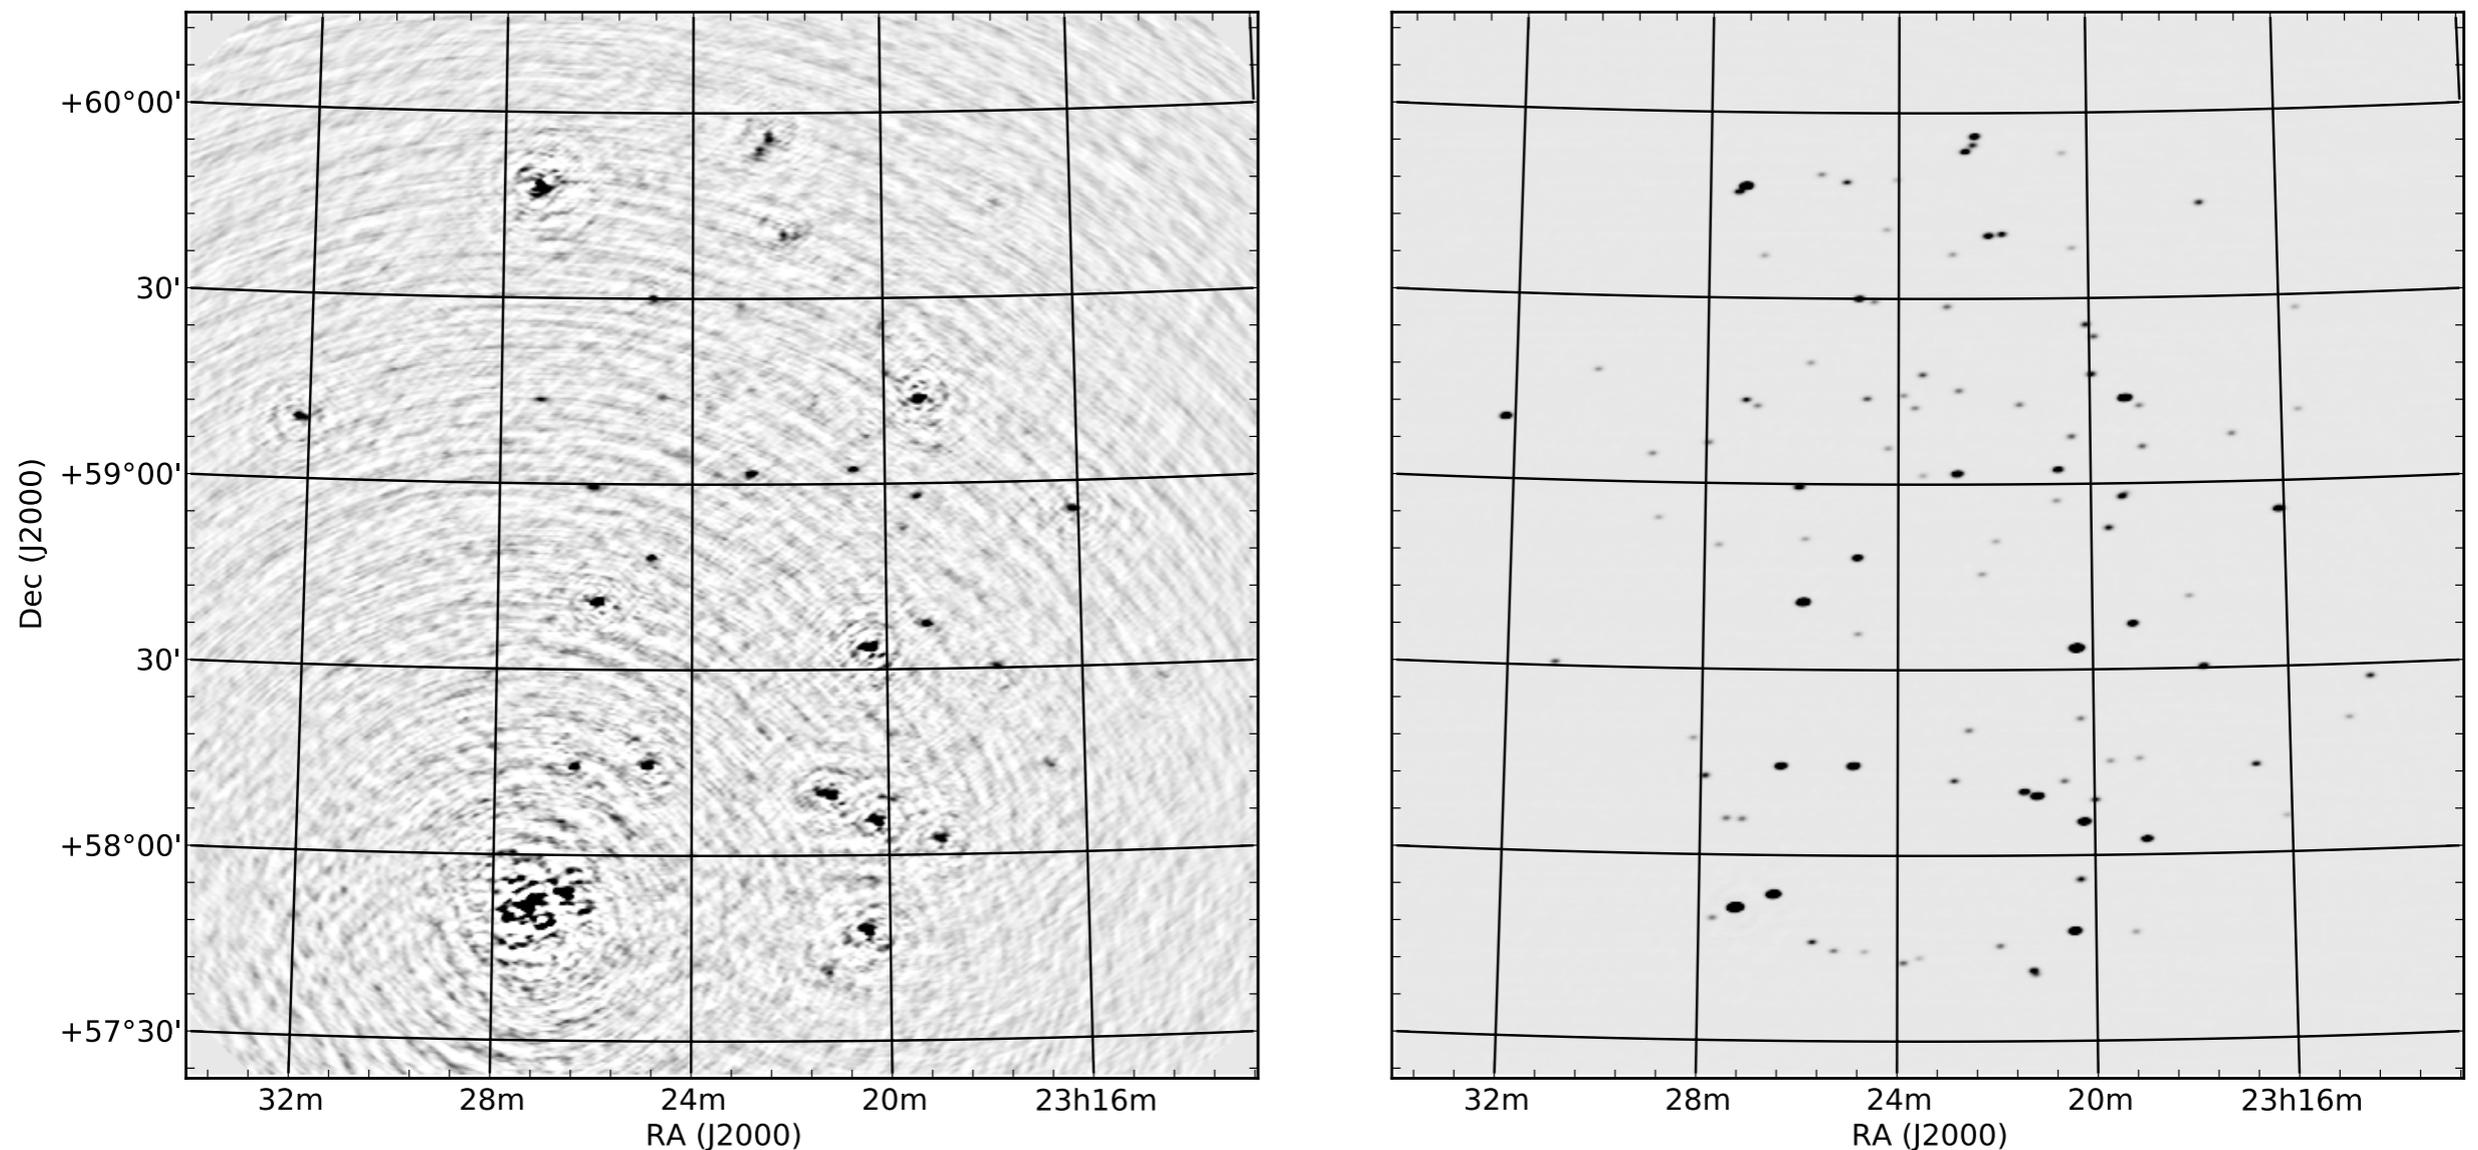

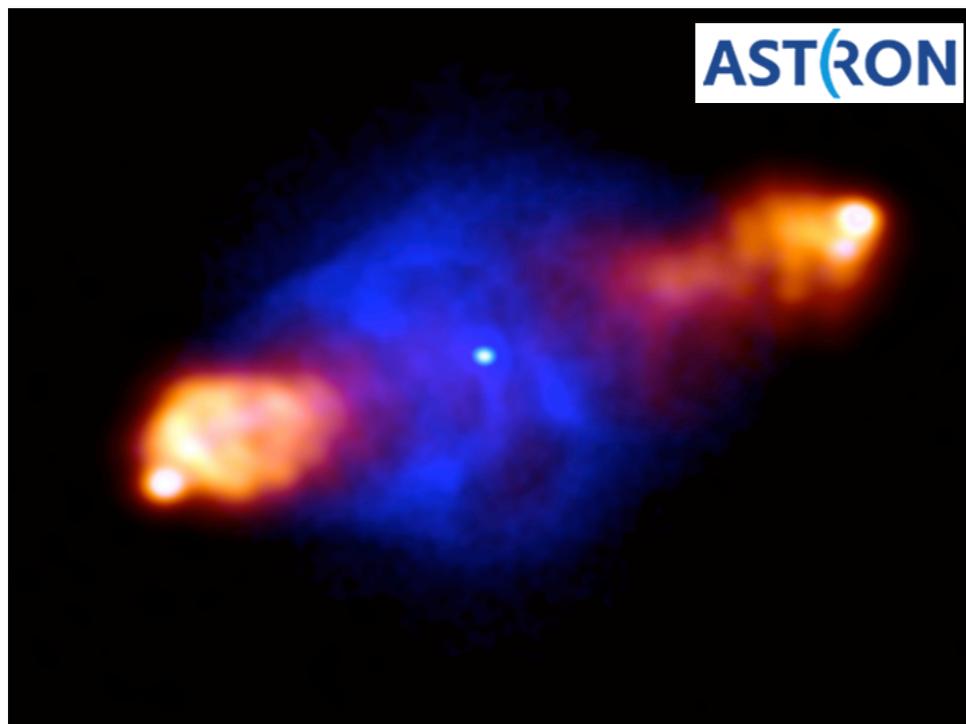

Fig. 6. This figure shows the deconvolved image synthesized from the simulated dataset described in Sec. 4.2.2. In the left panel, the ionospheric effects are not taken into account, and our deconvolution scheme naturally produces severe artifacts and high residuals in the reconstructed sky. The deconvolved image shown in the right panel has been estimated using our implementation of A-Projection with the time-dependent ionospheric phase screen.

Jupiter's radiation belts

LOFAR : $\Delta f = 127\text{-}172$ MHz), $\Delta t = 7\text{h}$, Beam = $17.8'' \times 15.5''$, Pixel = $1''$, Jupiter disk = $49''$

Contours @ 15 GHz [de Pater & Dunn, 2003]

Initial deep LOFAR observations of Epoch of Reionization windows: I. The North Celestial Pole

FoV $10^\circ \times 10^\circ$, $\Delta t = 6\text{h}$, $\Delta f = 115\text{-}163\text{ MHz}$, 25 stations

\Rightarrow sensitivity 0.1 mJy achieved ($\leq 1.5 \times$ thermal noise), using SageCal

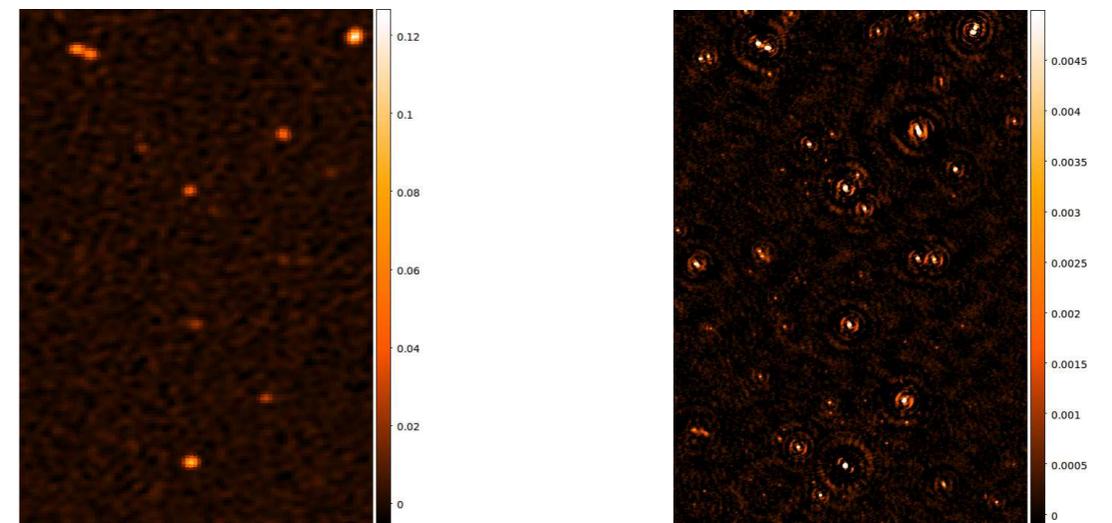

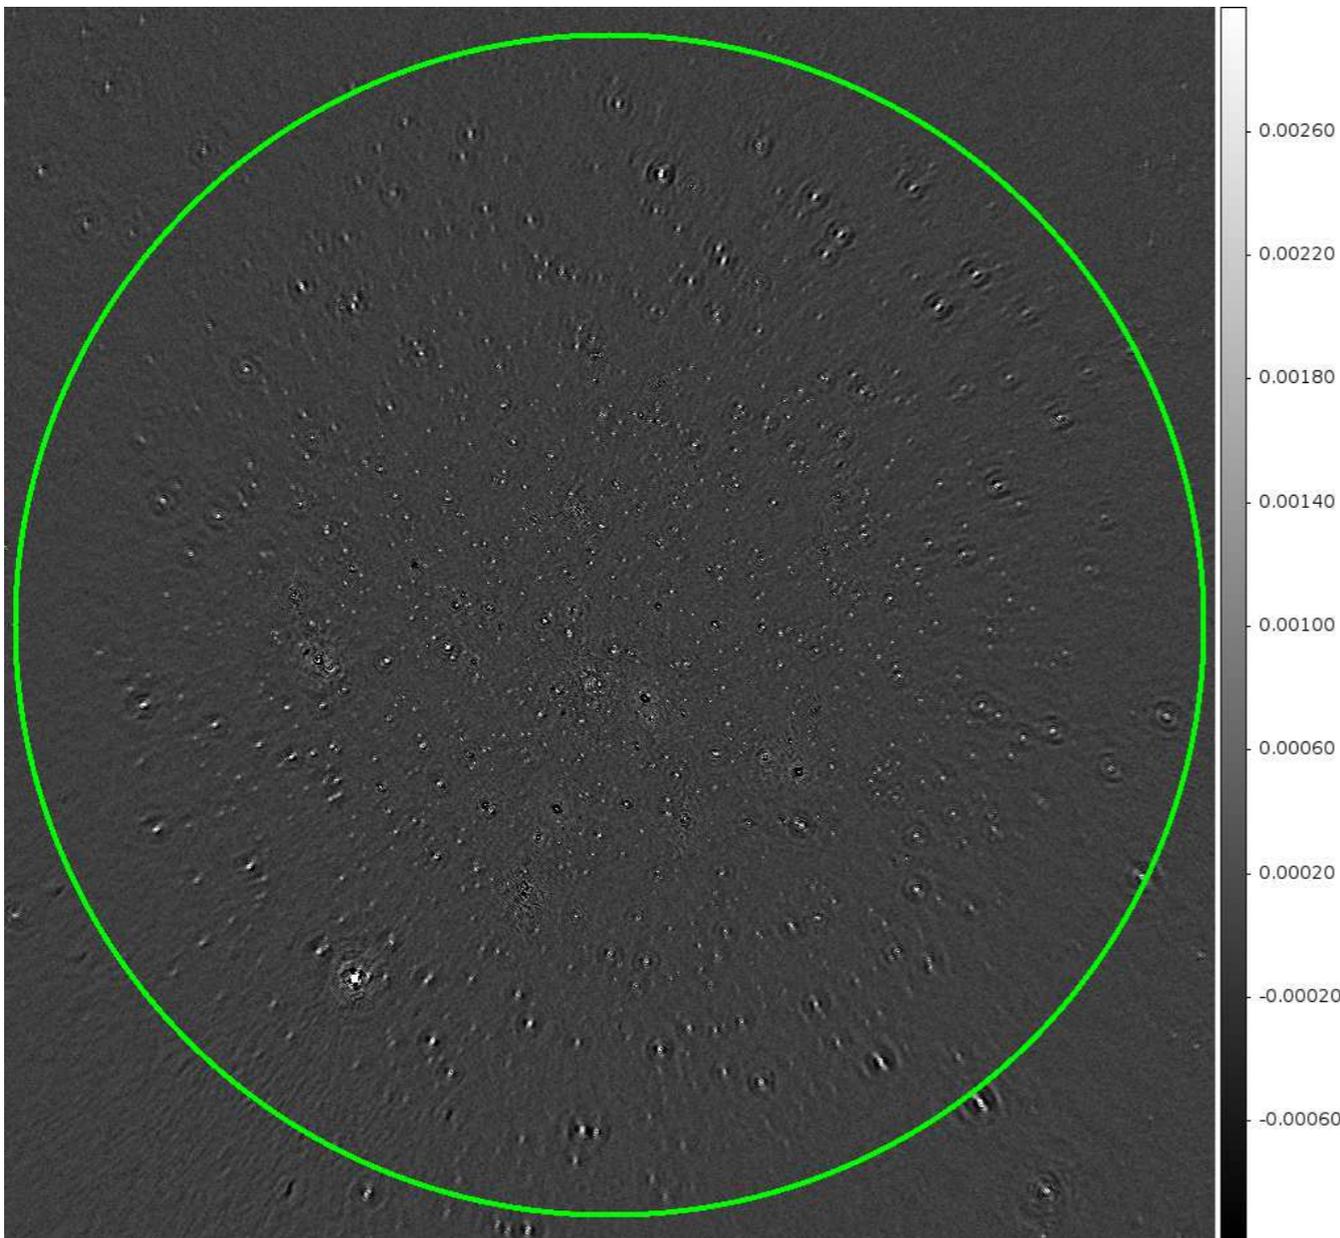

Fig. 11. Comparison of a small area of the NCP image, size 0.6×1.0 degrees with WENSS. The left panel shows the image from WENSS (PSF $60''$) while the right panel shows the equivalent image made using LOFAR (PSF $12''$). The colourbar units are in Jy/PSF. Many more sources, at much higher angular resolution can be detected.

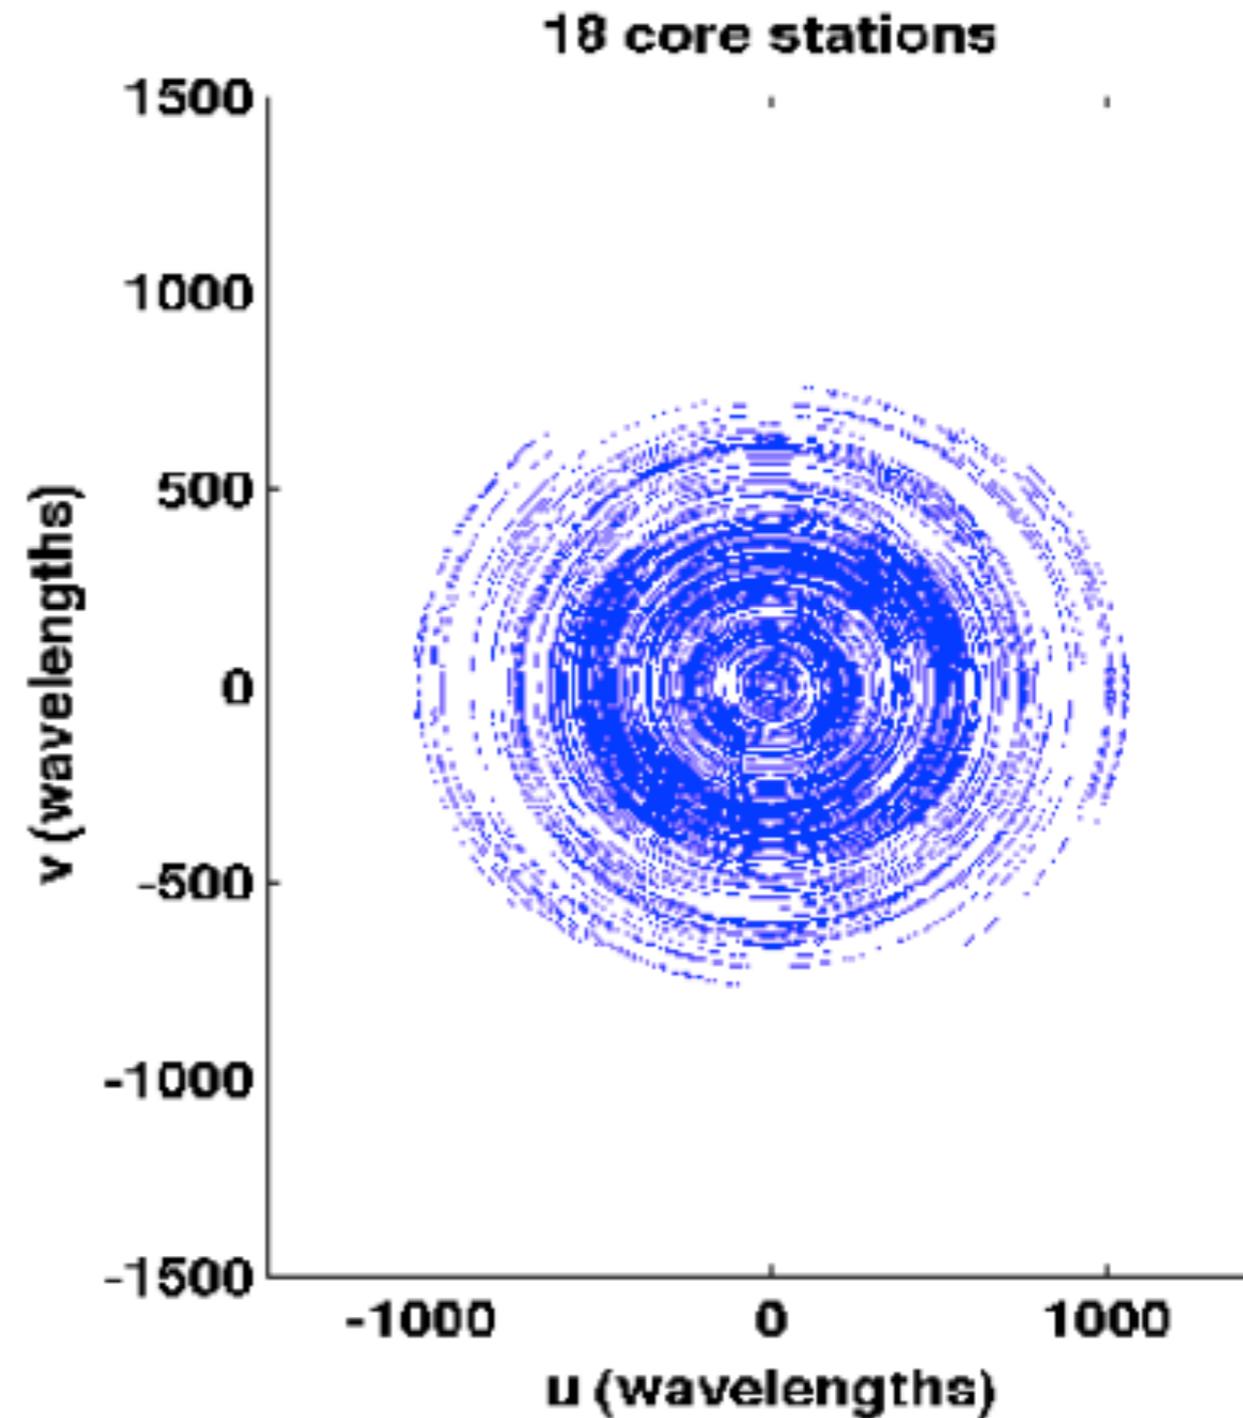

Yatawatta et al., 2013

Fig. 9. The NCP image after multi-directional calibration and source subtraction using SAGECal. After a shallow deconvolution using CASA (mainly to estimate the PSF), the skymodel is restored onto the image. The circle indicates an area of diameter 10 degrees. The image has 12000×12000 pixels of size $4''$ with a PSF of $12''$ and the noise level is about $100 \mu\text{Jy/PSF}$. Due to the fact that RS and CS beam shapes have different FOVs the sources at the edge of the image are distorted. In addition, due to frequency smearing, the sources at the edge of the image appear 'attracted' towards the center. The colourbar units are in Jy/PSF.

EoR Observation strategy

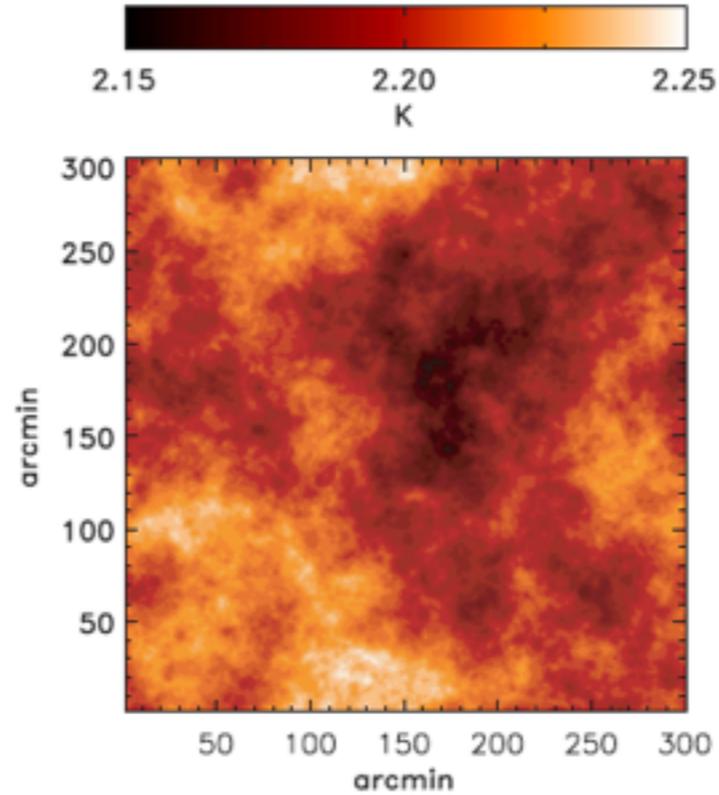

- LOFAR core (24 x 2 HBA)
- good u,v coverage required (1128 baselines)
- 115-190 MHz
- arcmin resolution
- 5 windows of 5° FoV (with low polarization)
- 10 kHz x 10 sec data
- 100s hours

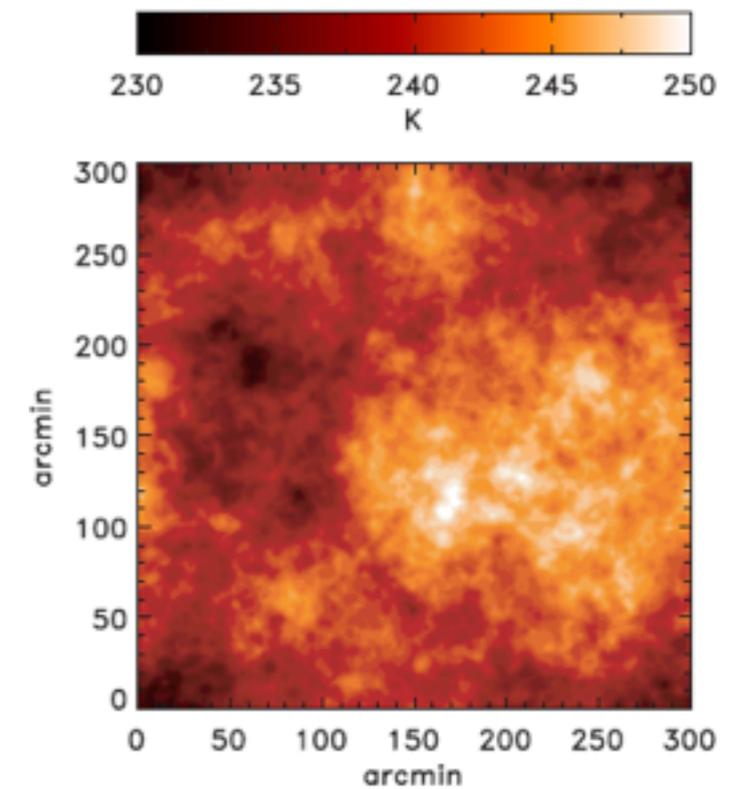

Foregrounds : simulations

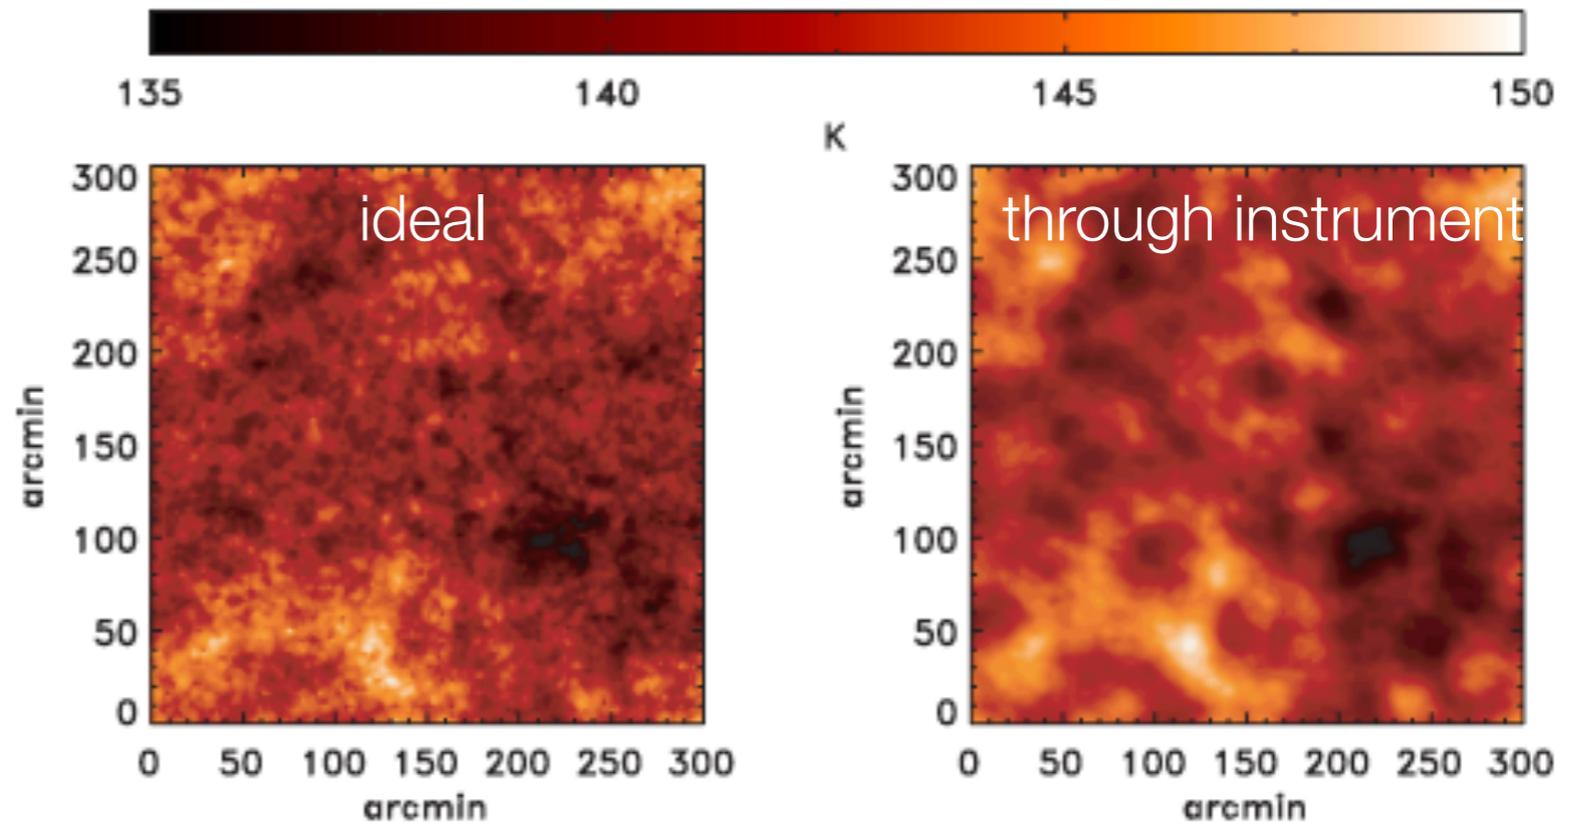

galaxies & clusters

galactic free-free

galactic synchrotron

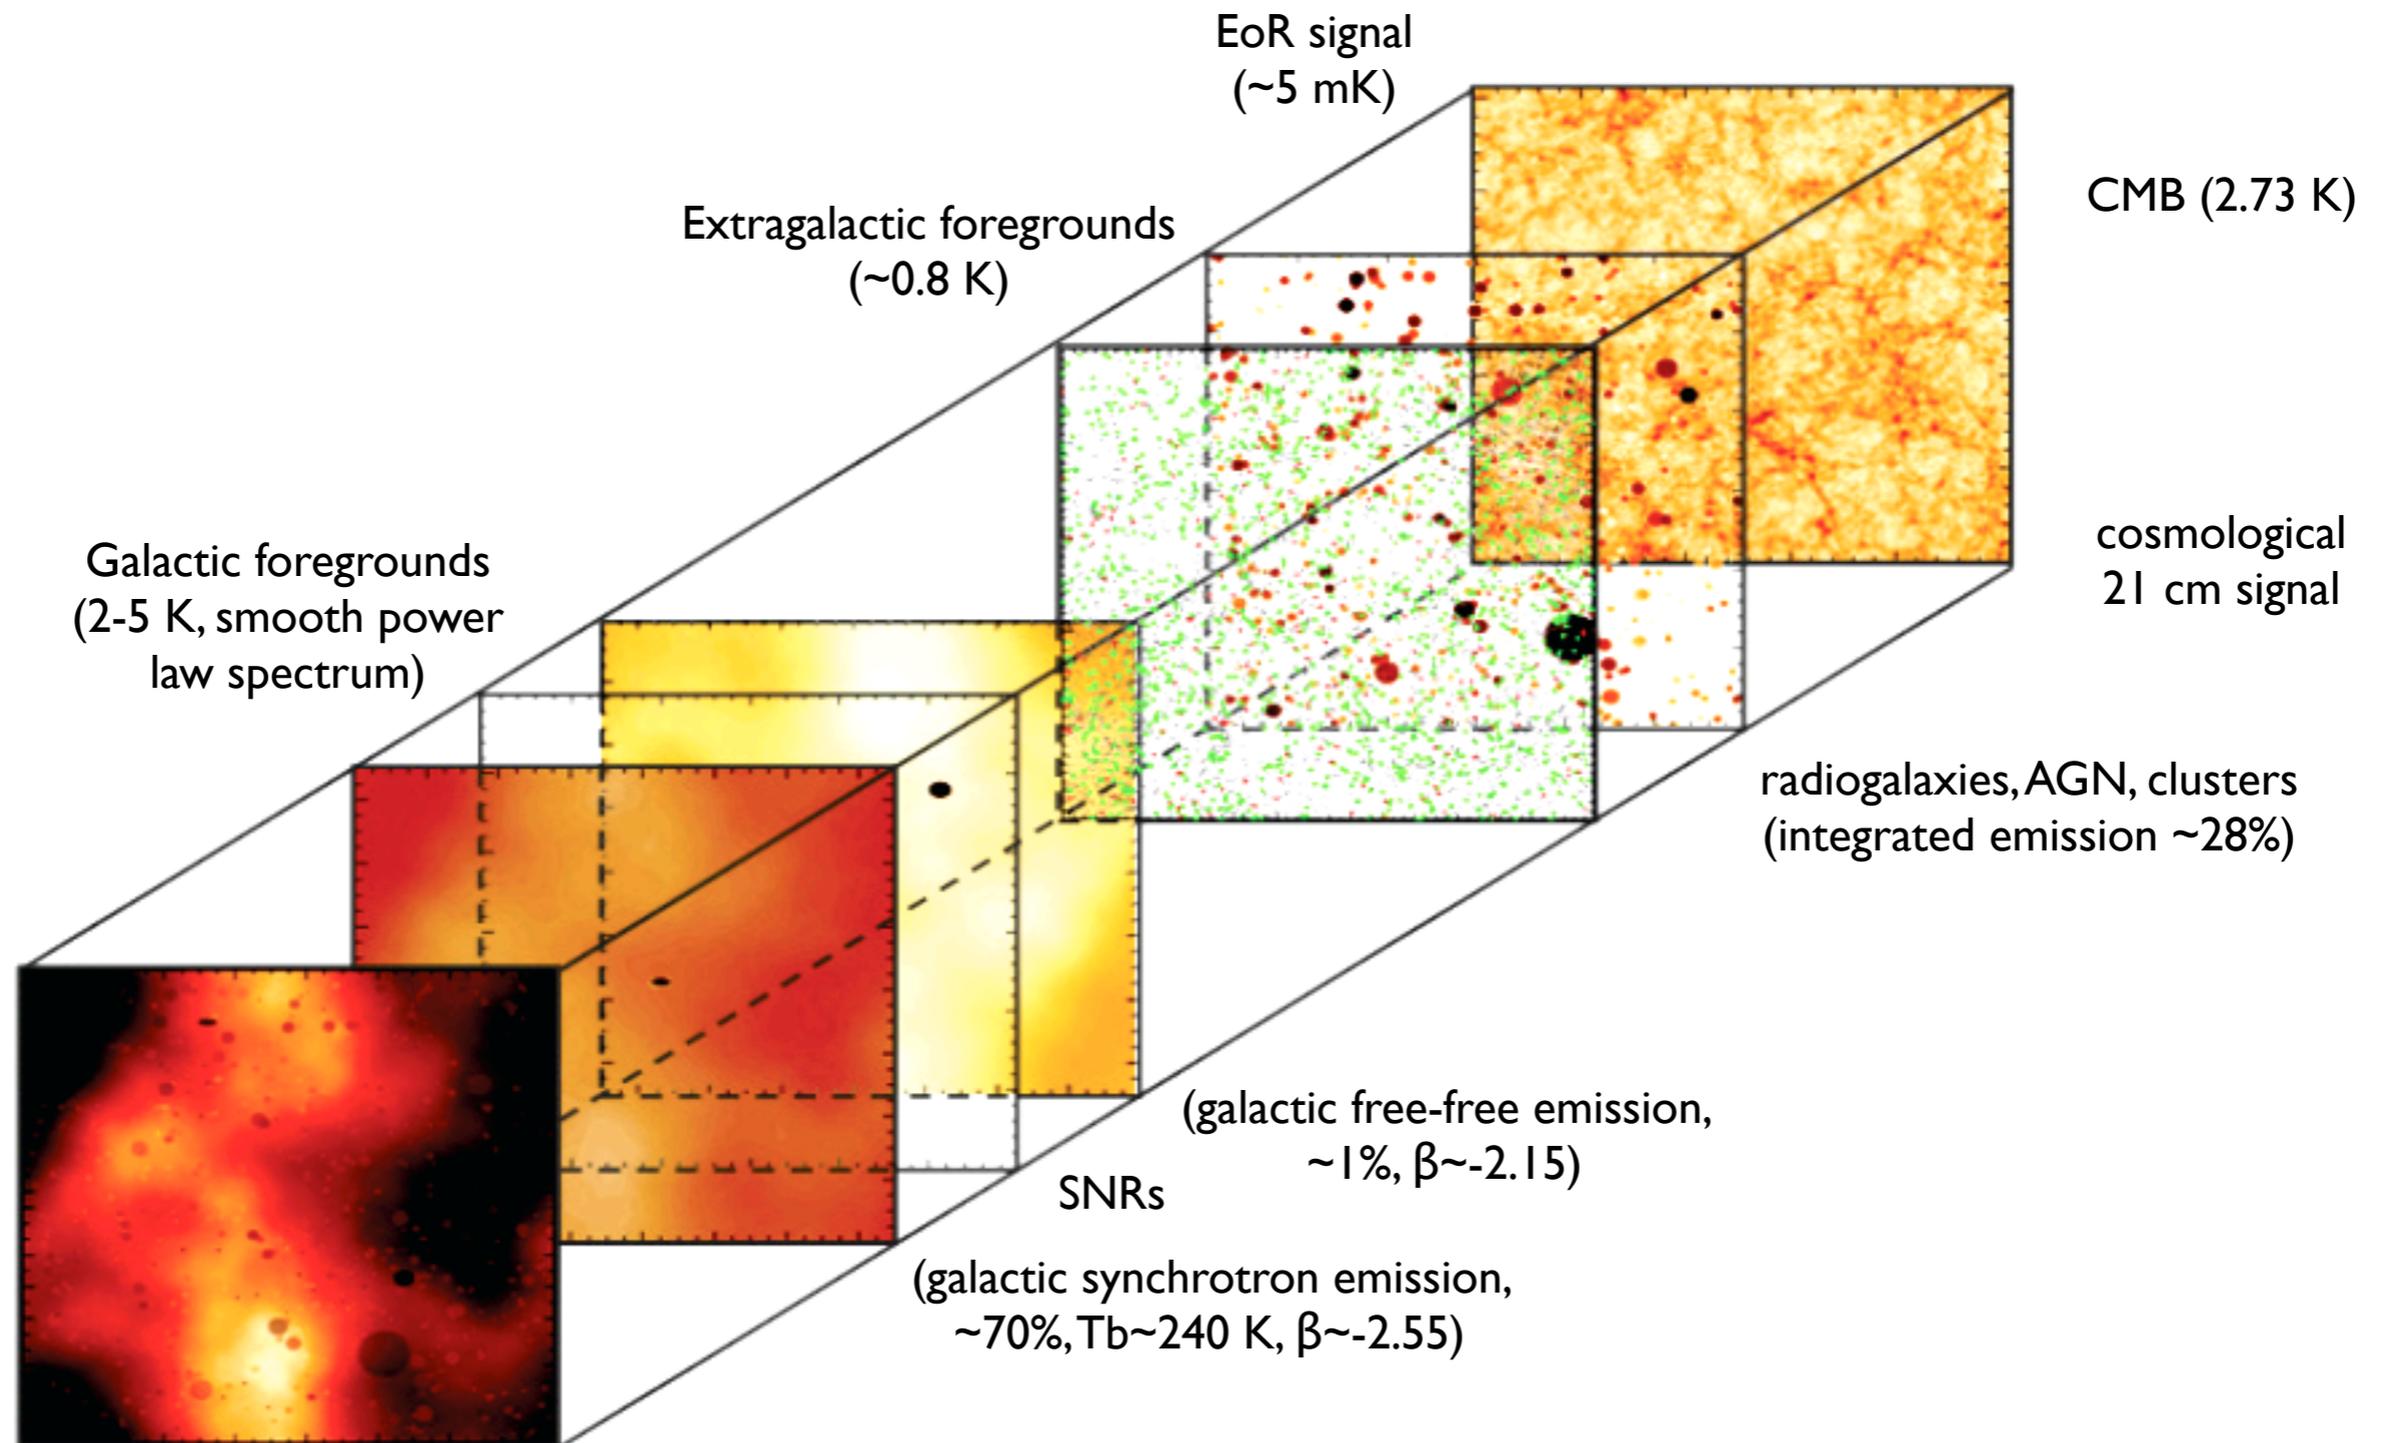

⇒ Simulated FG maps

- Pointing to zenith
- 150 MHz
- $\Delta t = 400$ h
- 100s averaging

Jelic et al, 2008

Foregrounds

$5^\circ \times 5^\circ$ FoV, $\sim 0.6'$ resolution, 115-180 MHz (here 120 MHz)

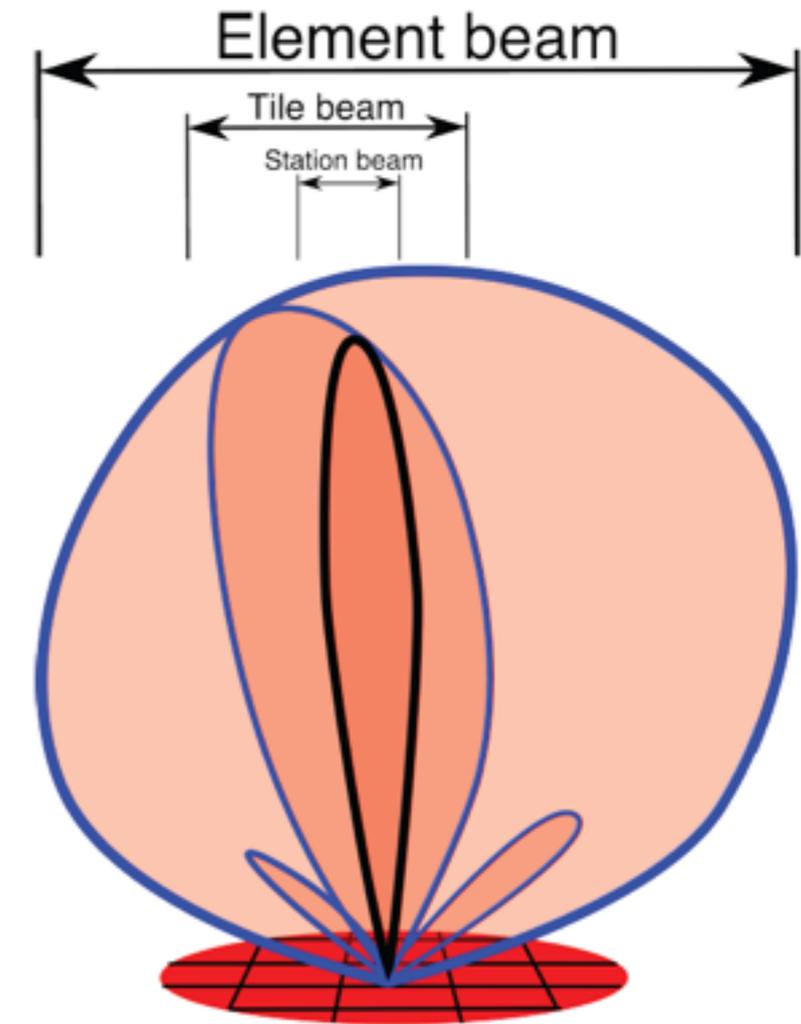

Effect of Foregrounds

**LOFAR - EoR
datacube**

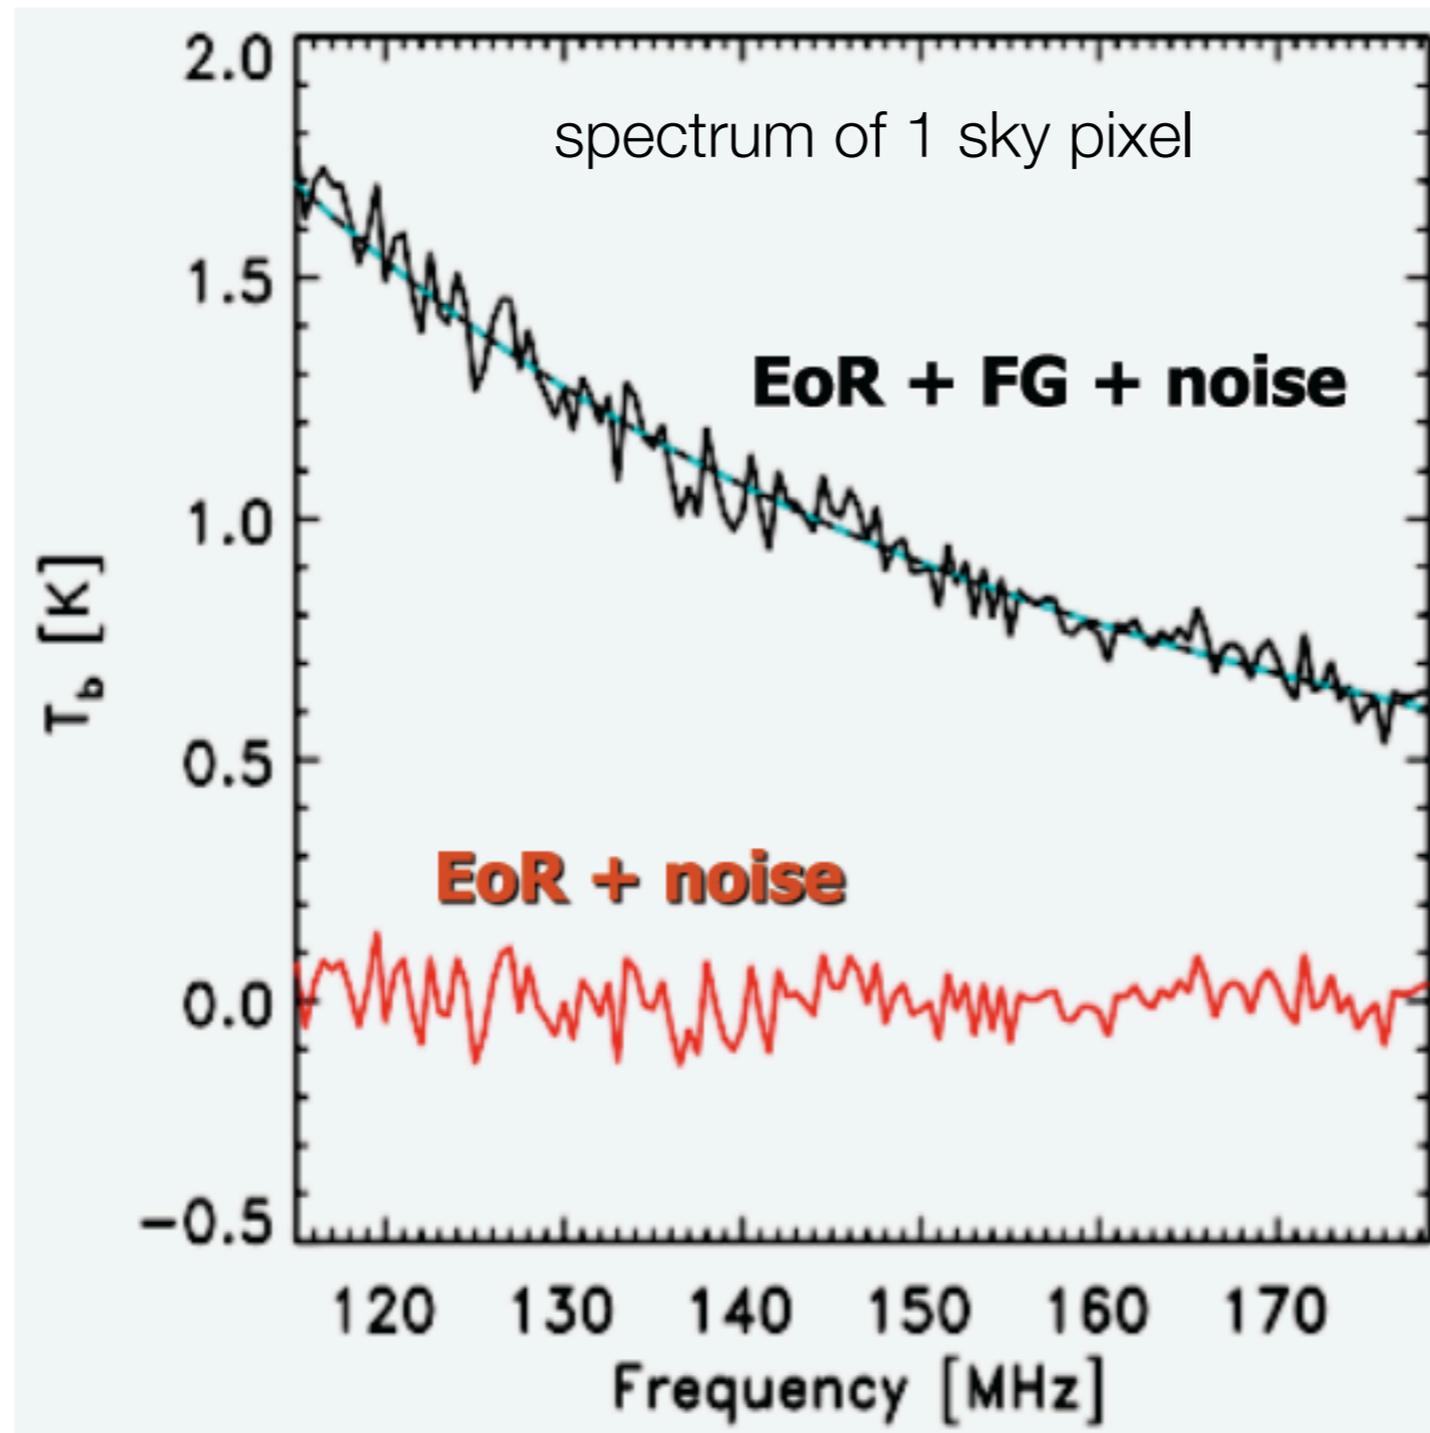

Analysis strategy

- Calibration +++ necessary (incl. ionosphere and beam model)
 - deep images (10^6 dyn. range)
- fit+filter foreground (smooth vs frequency per sky pixel)
- model residual noise
- extract sky (EoR) shifted 21 cm signal (unpolarized)

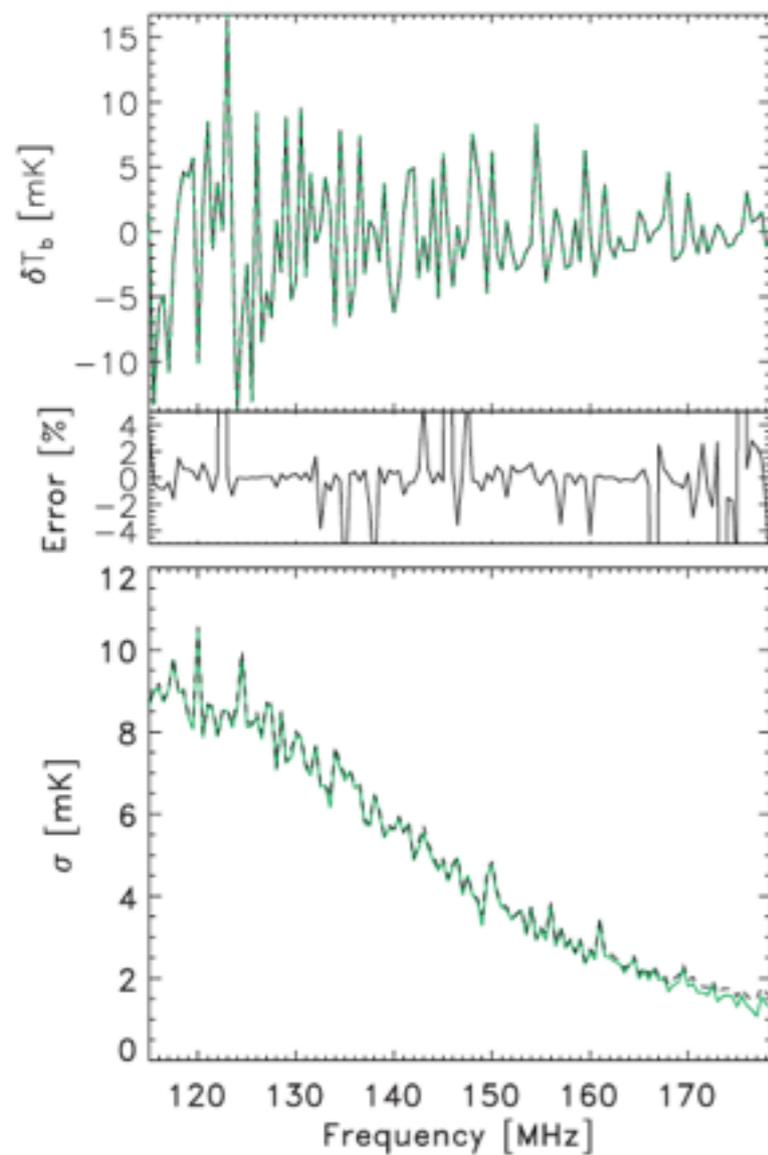

Statistical detection of EoR signal

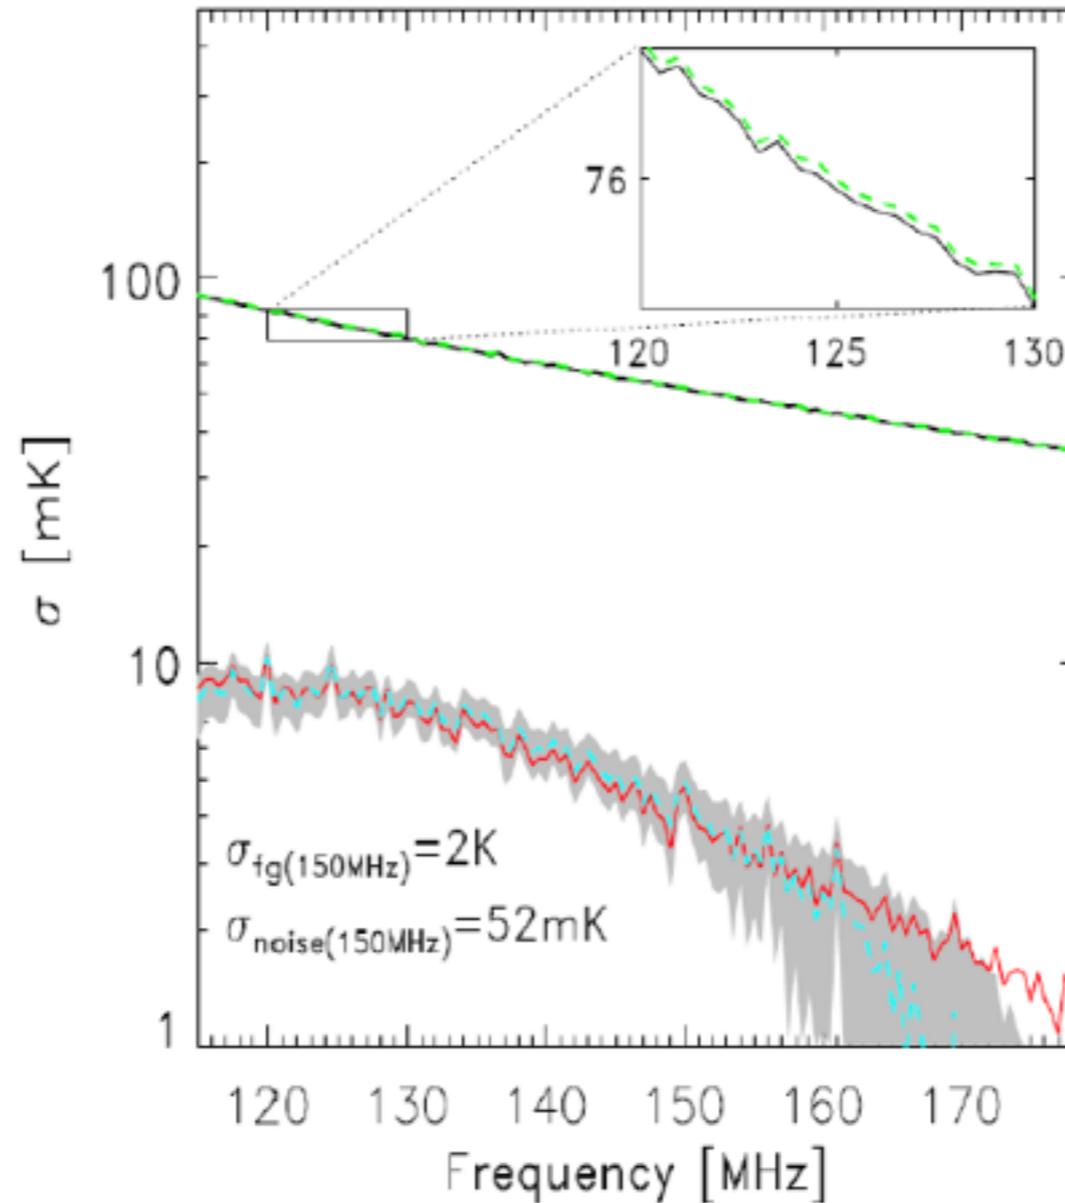

Jelic et al., 2008

- At 150 MHz: $T_{\text{EoR}} \sim 5$ mK, $T_{\text{FG}} \sim 2$ K, $T_{\text{noise}} \sim 50$ mK
- Hypotheses : diffuse FGs only in total intensity, perfect instrument & calibration

Statistical detection of EoR signal

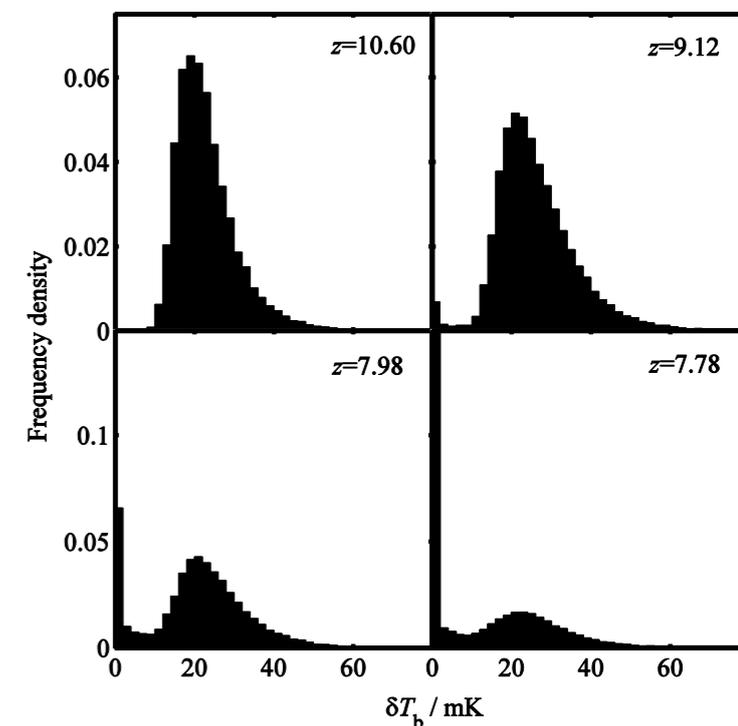

- Modelled EoR signal for 1 pixel & sigma over map

- Noise modelling
- EoR signal extraction (input EoR signal = red, retrieved = gray, avg = blue)
- Possible use of skewness

Jelic et al., 2008

Harker et al., 2008

WELCOME TO THE LOFAR EoR KSP

[Also available in presentation mode.](#)

LOFAR, the [LOW Frequency ARray](#) radio telescope, will observe the Epoch of Reionization (EoR) at redshift, through the hydrogen hyperfine transition. This is a very challenging observation and analysis task, requiring high resolution. Each field will contain about 1000 sources.

The EoR measurement is very challenging. The main challenges are:

1. The signal will be contaminated by foregrounds.
2. The sky signal goes through an ever changing ionosphere that can severely distort the signal.
3. Given the nature of the LOFAR instrument, modeling the telescope with time will be very challenging.
4. The thermal noise per resolution element, even after hundreds of hours of observation will dominate over the signal.

All these issues have to overcome before a reliable detection of the EoR could be claimed.

Le concept de Super Station LOFAR : réseau phasé + interféromètre géant à Nançay

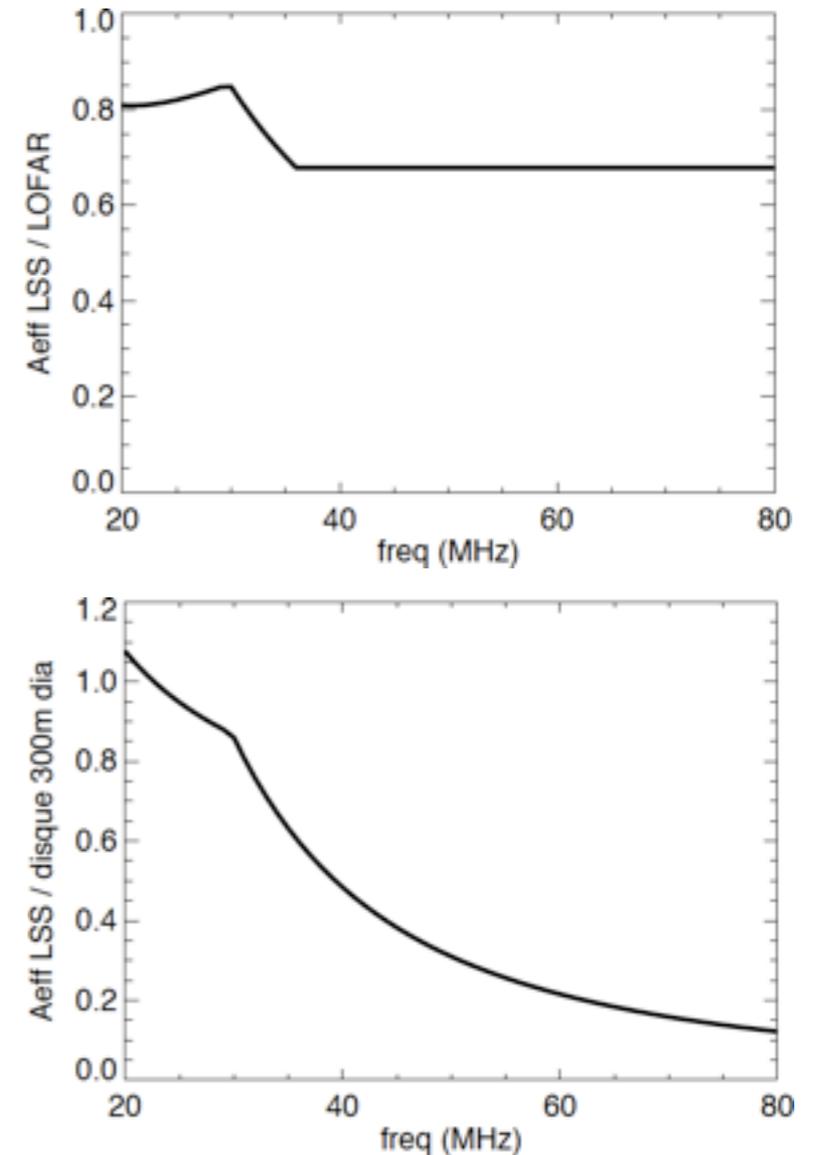

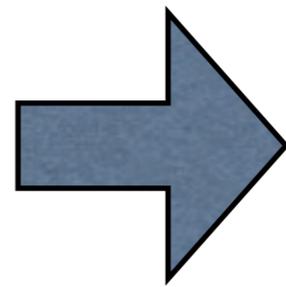

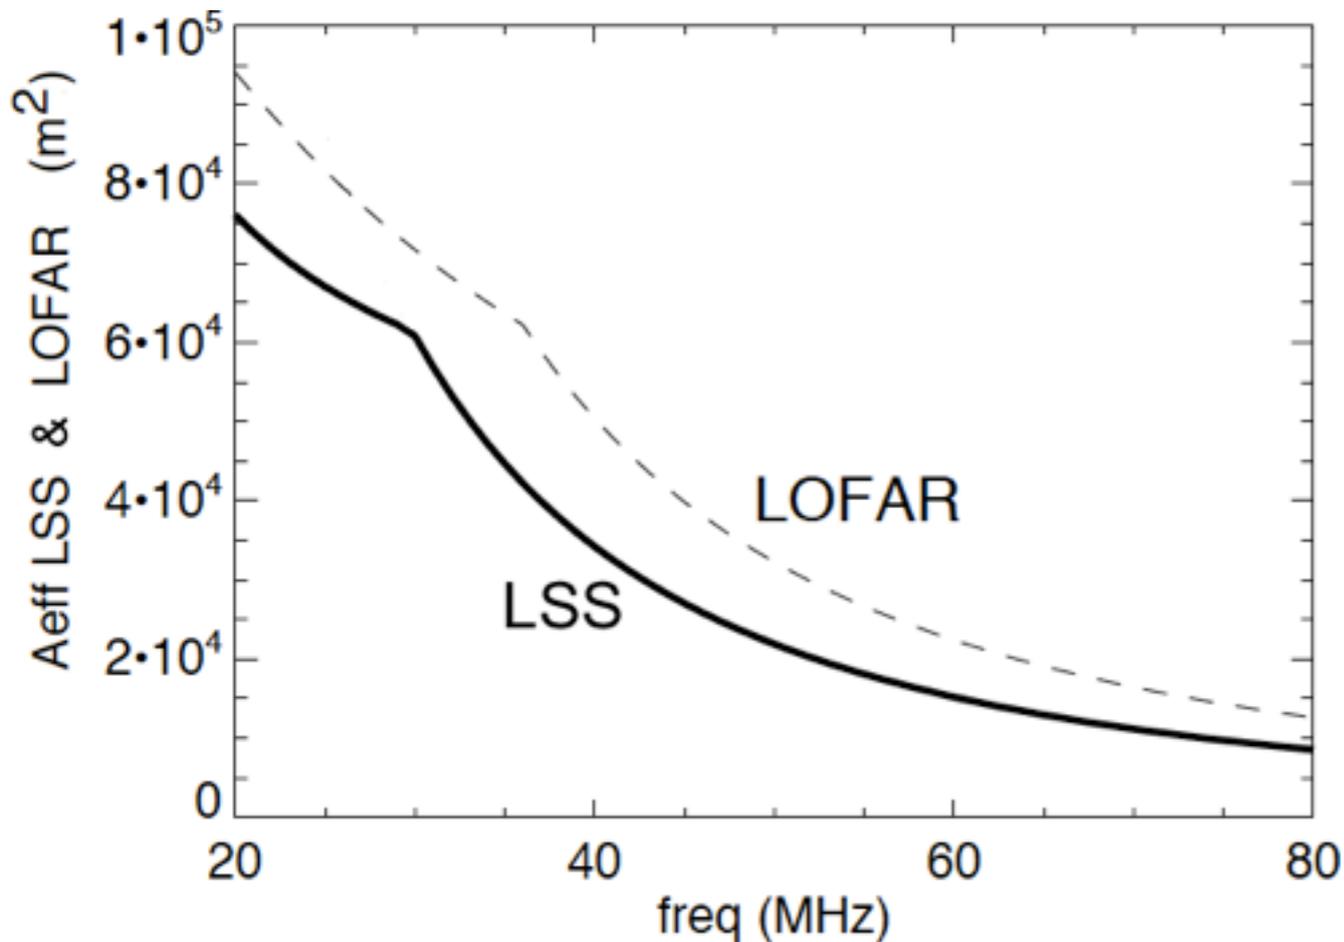

Les apports de la LSS/NenuFAR

- Bases longues $19^{1/2}$ x plus sensibles
 - ⇒ sensibilité globale $\sim x2$
 - ⇒ meilleure imagerie haute résolution
- LSS comme 2ème coeur
 - ⇒ + $\sim 1/3$ de temps d'observation
- Bases courtes intra-LSS
 - ⇒ structures étendues ($>10^\circ$)

Les apports de la LSS/NenuFAR

Grand instrument autonome : « Arecibo à Nançay »

⇒ ~19x la sensibilité d'une station internationale en LBA

⇒ $A_{\text{eff}} = 70-80\% \times A_{\text{eff}} \text{ LOFAR LBA} = 190\% \times A_{\text{eff}} \text{ Coeur LOFAR LBA}$

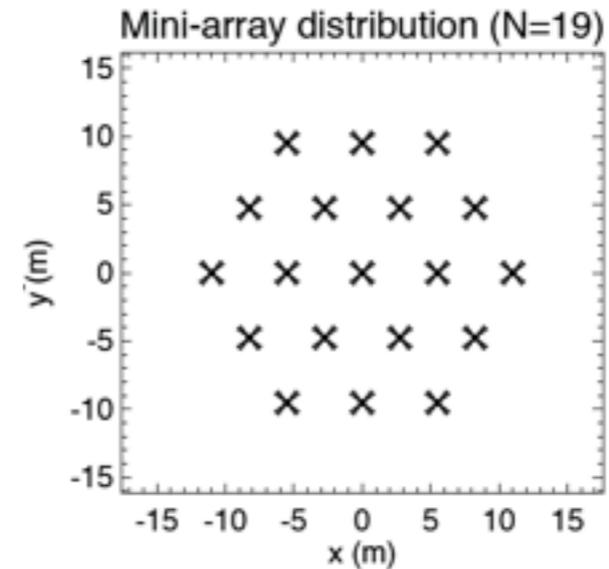

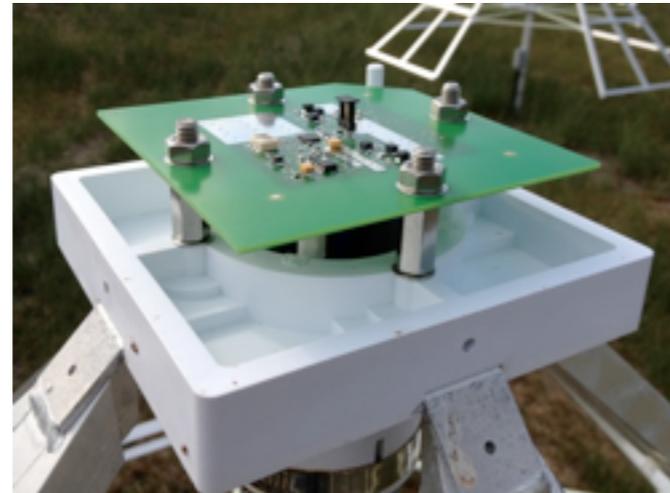

(mode faisceau cohérent > 2x+ efficace que LOFAR)

Accès aux TBF (15-80 MHz)

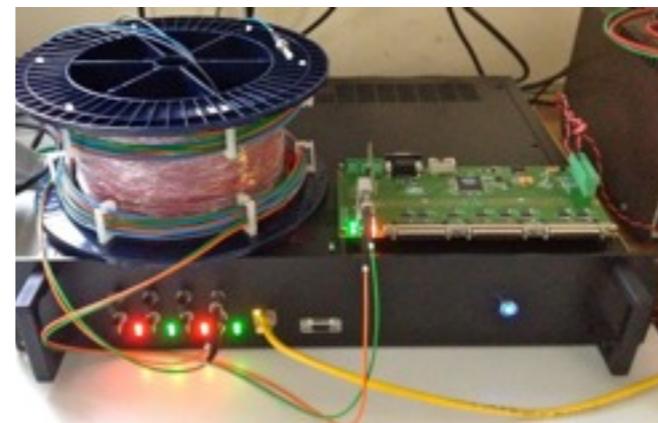

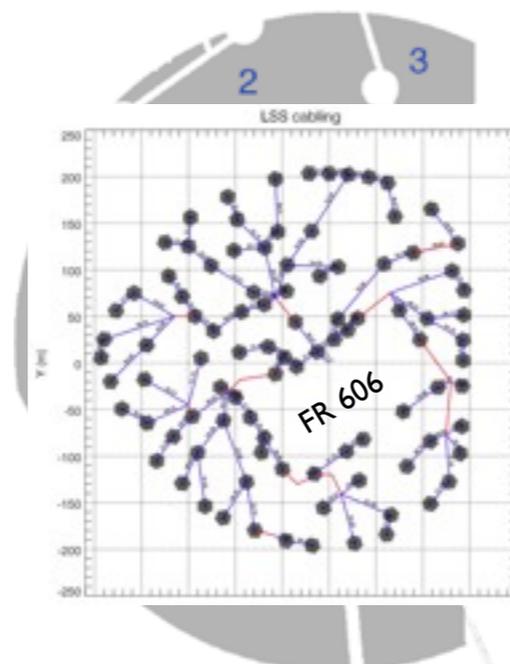

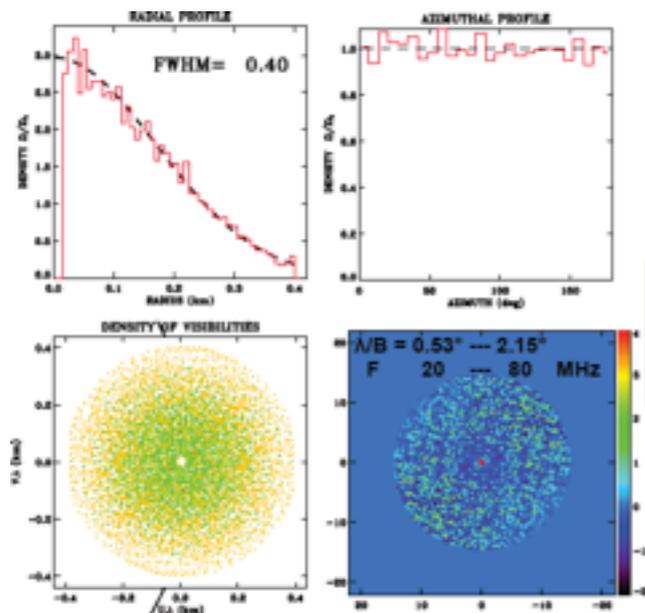

Design + Prototype de la LSS/NenuFAR

programme ANR 9/2009 - 2/2013 - 500 k€

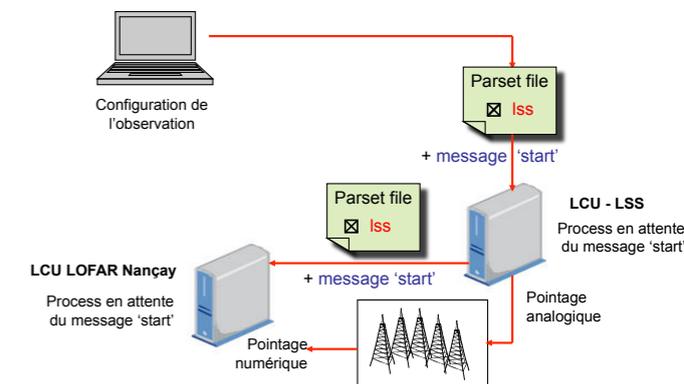

<http://www.obs-nancay.fr/lss/>

- Etude de tous les aspects du projet : antenne, préampli, distribution mini-réseau & globale, phasage, câblage/tranchées, contrôle/commande silencieux, dialogue/LOFAR

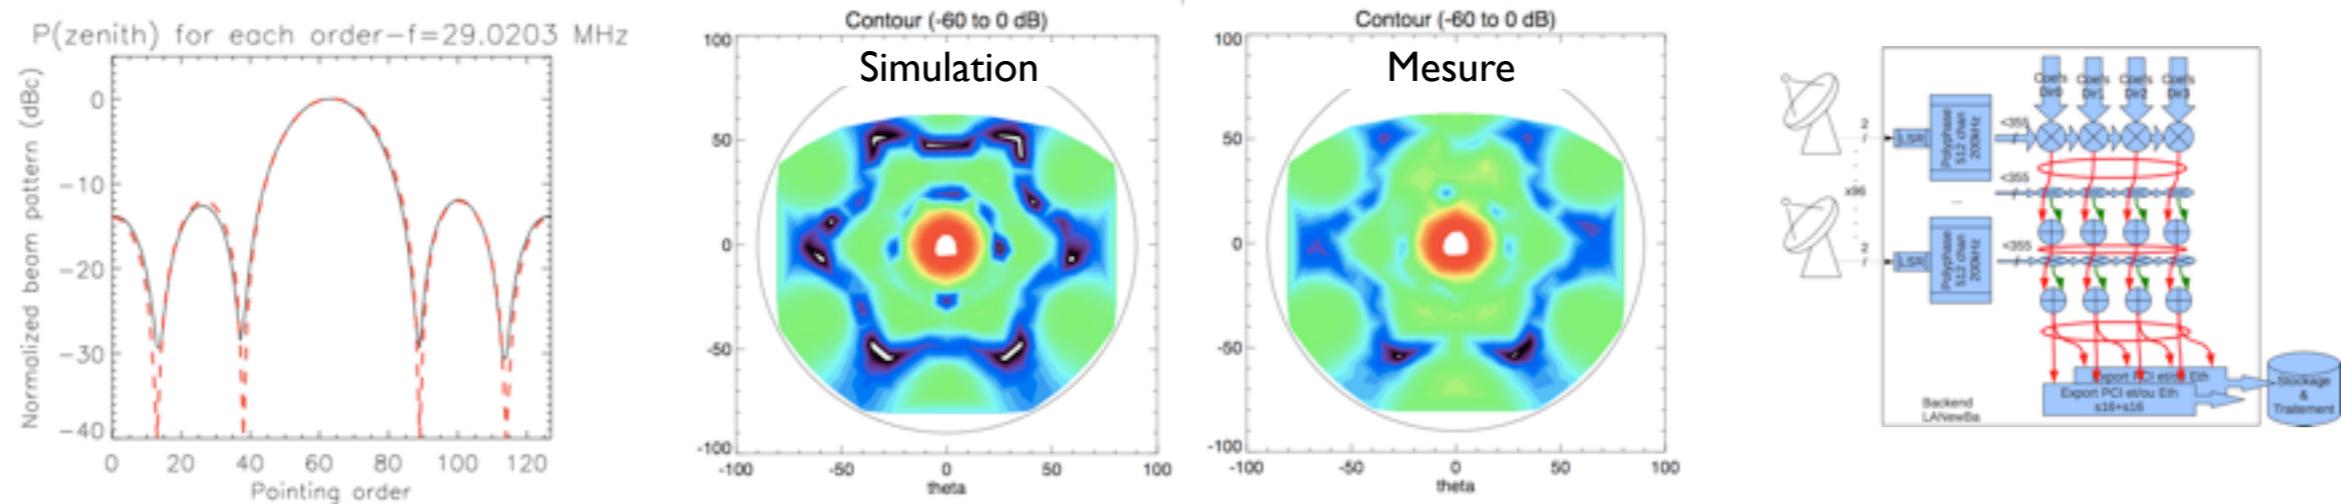

Mode standalone

Design + Prototype de la LSS/NenuFAR

programme ANR 9/2009 - 2/2013 - 500 k€

<http://www.obs-nancay.fr/lss/>

- Construction de 3 mini-réseaux (x 2 polarisations) + récepteur de test dédié
- Définition d'un récepteur autonome dédié (Nancay/ALSE)
⇒ "duty-cycle" ~100% dans le faisceau analogique mini-réseau (~30° @ 30 MHz)
- Études industrialisation, site (ONF), chiffrage, sous-traitance, calendrier

LSS/NenuFAR dans le contexte national & international

Equipe LSS-France : ~ 25 chercheurs + 15-20 ITA

Laboratoires impliqués dans la réalisation : Nançay, LESIA, GEPI, LERMA, LPC2E, Prisme, Subatech, IRA Kharkov, SRI Graz (soutien OP, ESEP) ⇒ Axe Paris(Meudon)-Orléans-Nançay, en vue de SKA

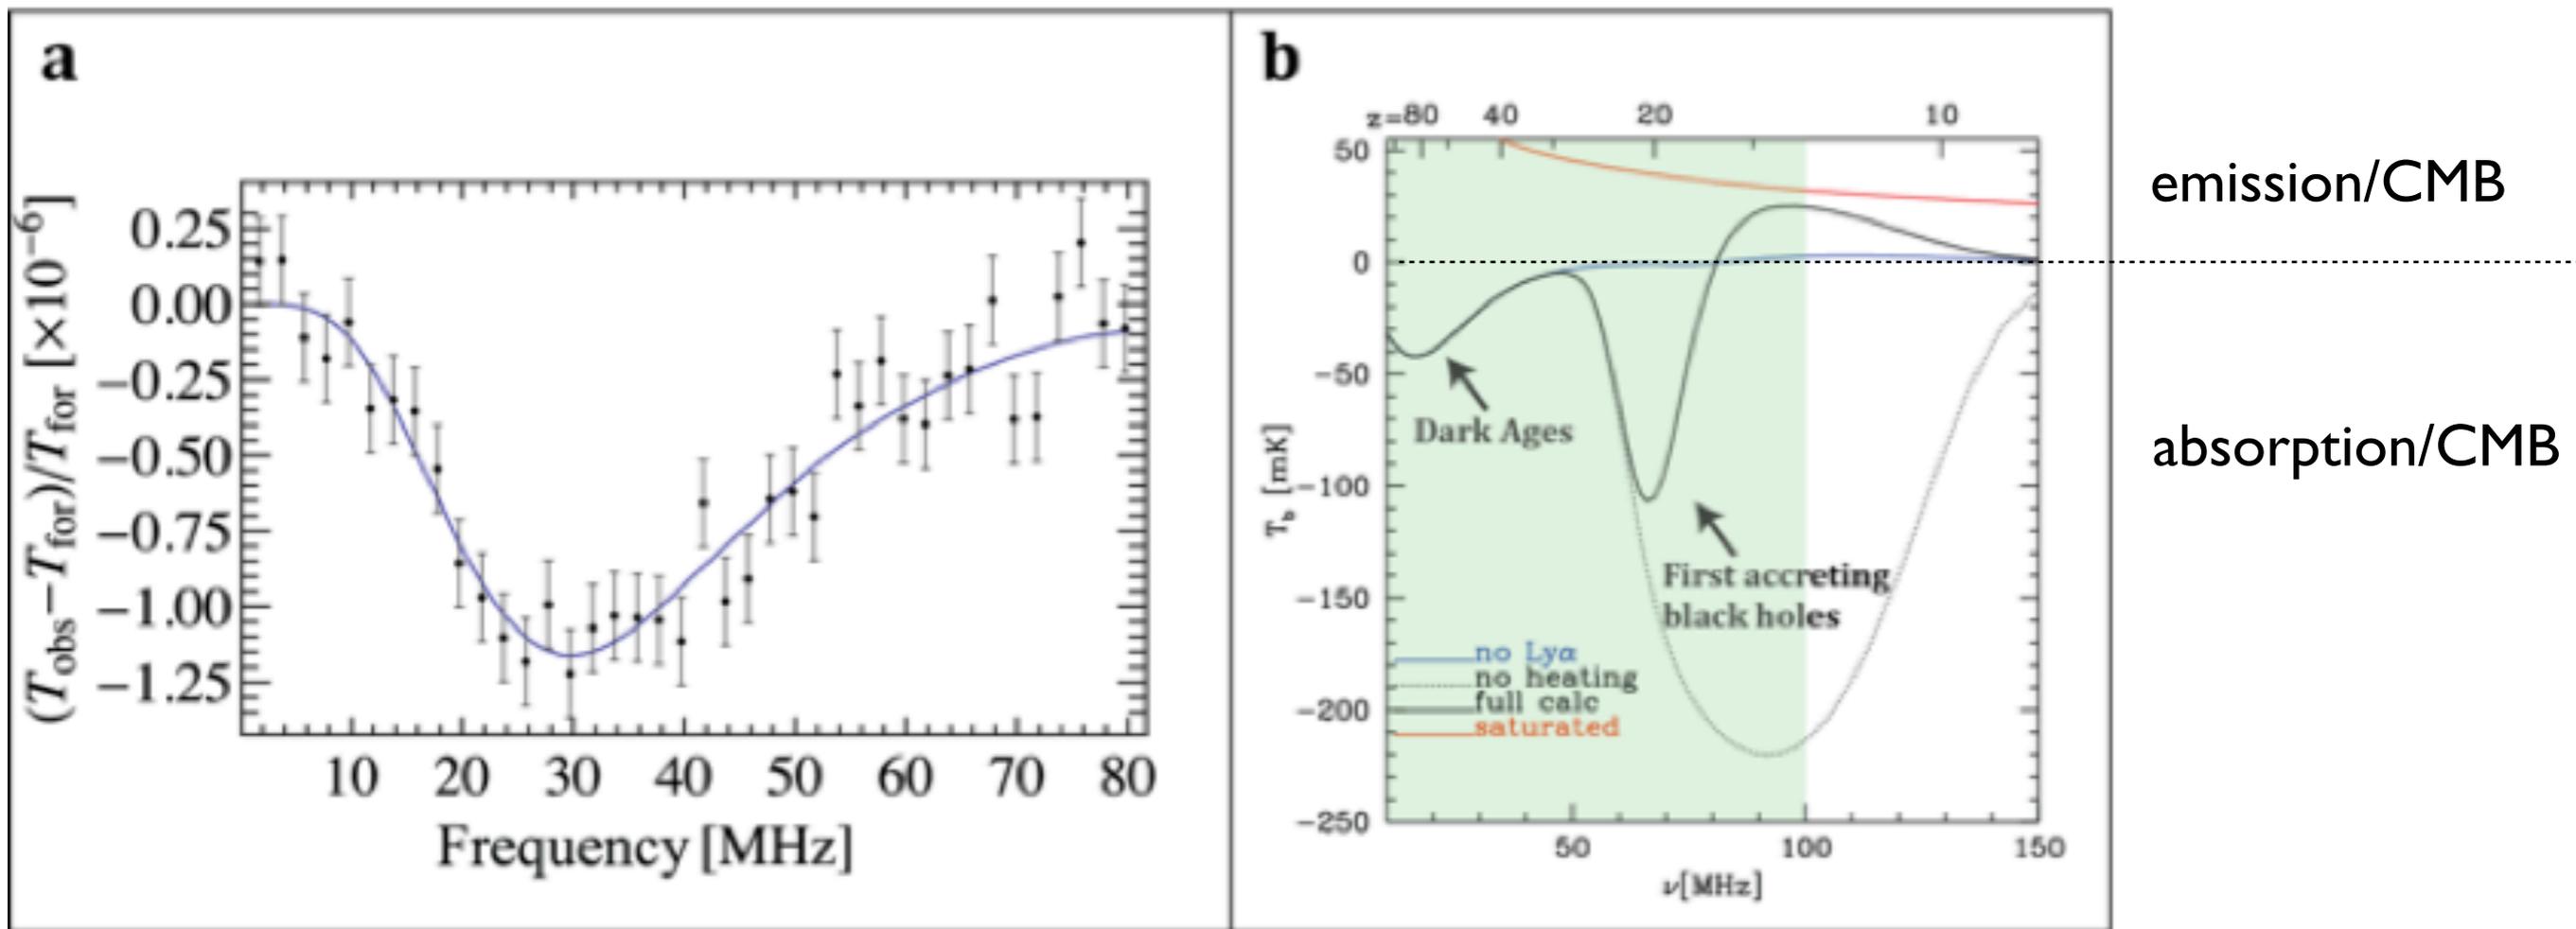

(LSS = précurseur scientifique et technique de SKA)

Laboratoires utilisateurs : OP (LESIA, GEPI, LERMA, LUTh), CEA/Sap-DASE-AIM, IAS, IAP, E. Polytechnique, ENS/LRA, APC, IN2P3, LPC2E, Nançay, OCA, IRAP ...

LSS/NenuFAR & Late Dark Ages

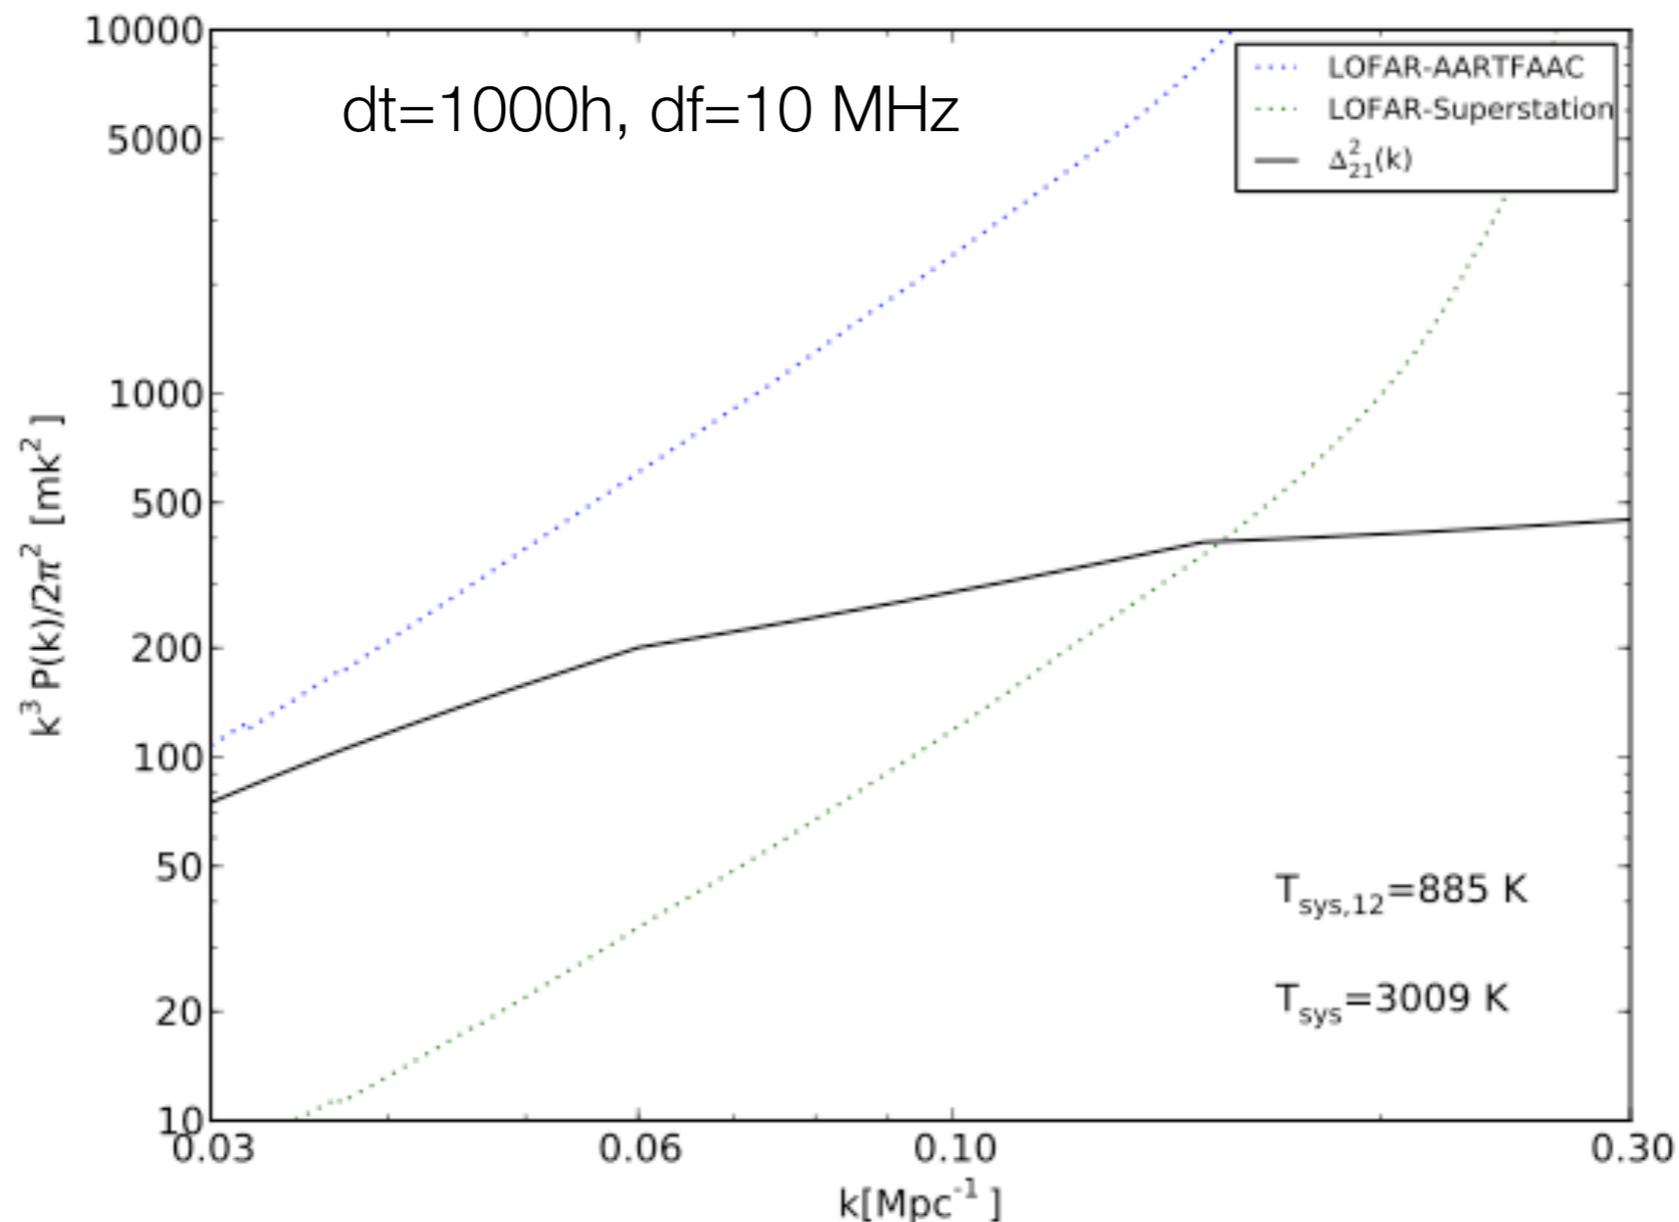

Pritchard & Loeb, 2008, 2010

- Total (all-sky) intensity H_I for $z \geq 12-20$ (Late Dark Ages) : δT_b up to (-)100 mJy in LBA range
⇒ detectable in hours with a phased array (station)
- But requires accurate bandpass calibration (at 10^{-6} level), via measurement of auto- & cross-correlations on noise source (laboratory or A team)

⇒ **LSS Standalone !**

LSS/NenuFAR & Late Dark Ages

Sensitivity of LOFAR-AARTFAAC and the LOFAR-Superstation z=20

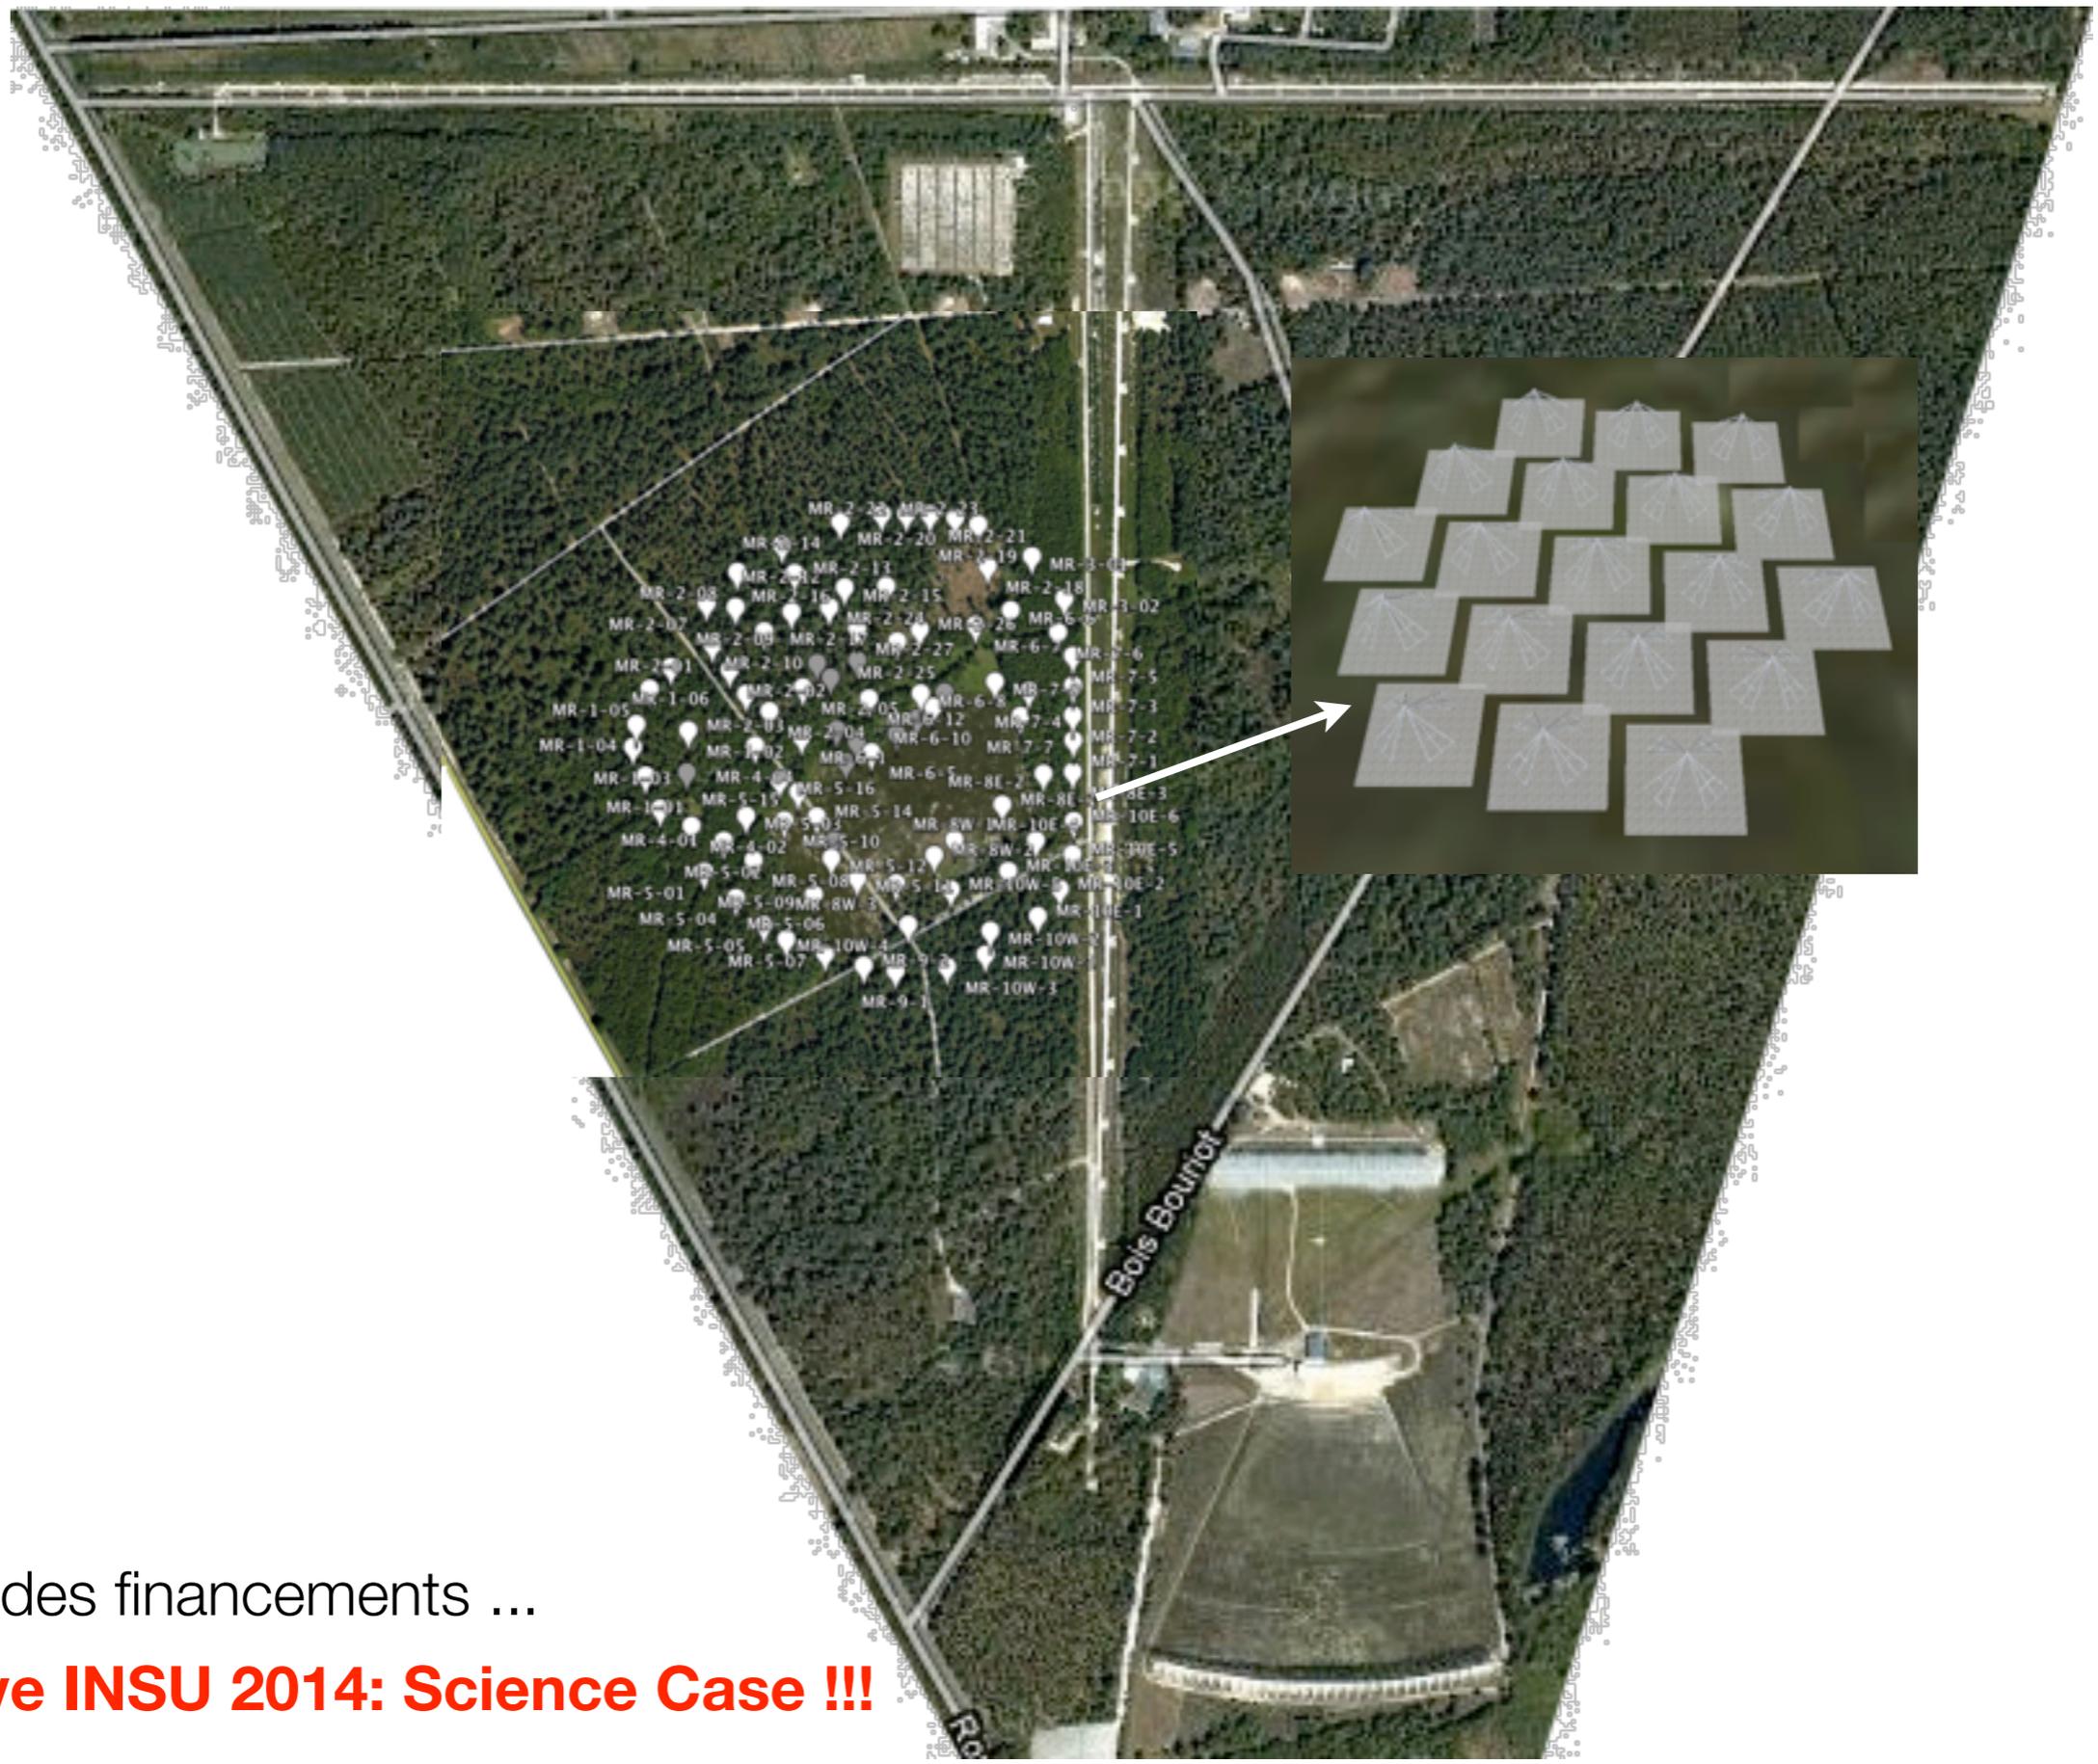

Visbal et al., 2012
 McQuinn et al., 2012

courtesy L. Koopmans

$$\Delta_{\text{Noise}}^2 = \left(\frac{2}{\pi}\right) k^{3/2} [D_c^2 \Delta D_c \times \Omega_{\text{FoV}}]^{1/2} \left(\frac{T_{\text{sys}}}{\sqrt{Bt_{\text{int}}}}\right)^2 \left(\frac{A_{\text{core}} A_{\text{eff}}}{A_{\text{coll}}^2}\right)$$

- Spatial fluctuations of H_I at z~20 possibly larger than previously thought
 ⇒ **Possibly detectable with LSS due to large collecting area**

Demain la LSS/NenuFAR ?

Prospective INSU 2014: Science Case !!!

LOFAR - LSS/NenuFAR in France

FLOW : Tagger, Zarka, Theureau et al.

Action Spécifique SKA-LOFAR : Corbel, Charlot, Zarka et al.

	Mardi 4 Juin
14h00-14h30	Mickael Wise (Invité): LOFAR's First Year of Operations: A Gallery of First Science
14h30-14h50	Jean-Mathias Griessmeier: Low frequency pulsar observations with LOFAR
14h50-15h10	Philippe Zarka: LOFAR imaging issues and first extragalactic observations
15h10-15h30	Giulia Macario: The LOFAR's view of galaxy clusters
15h30-15h50	Julien Girard: Jupiter's synchrotron emission: a practical example of science and data reduction with LOFAR
15h50-16h00	Jean-Mathias Griessmeier: Observing with LOFAR in local and in international mode
16h-16h30	<i>Pause café</i>
16h30-17h00	Thijs van Der Hulst (Invité): Probing cosmology and galaxy evolution with HI using SKA and SKA Pathfinders
17h00-17h20	Steve Torchinsky: Results from EMBRACE@Nancay
17h20-17h40	Dominique Aubert: Simulation of the BAO 21 cm signal during the epoch of reionization
17h40-18h00	Yannick Libert: High-resolution imaging of circumstellar environments around AGB stars at 21 cm
18h00-18h15	Mamta Pommier: Low Frequency Radio observations in galaxy clusters
